IN TWO SECTIONS—SECTION TWO

TRANSACTIONS

of The American Society of Mechanical Engineers

SOCIETY RECORDS—Part III

(Including Indexes to Publications)

[Part I of Society Records for the year 1936 (containing Council and Committee Personnel and other general information) was issued as Section Two of the Transactions for February, 1936, and Part II (Memorial Notices), August, 1936.]

JANUARY, 1937

VOL. 59, NO. 1

Published by The American Society of Mechanical Engineers

TRANSACTIONS

of The American Society of Mechanical Engineers

Published on the tenth of every month, except March, June, September, and December

Publication Office, 20th and Northampton Streets, Easton, Pa.
Editorial Department at the Headquarters of the Society, 29 West Thirty-Ninth Street, New York, N. Y.

Includes Aeronautical Engineering

Entered as second-class matter March 2, 1928, at the Post Office at Easton, Pa., under the act of August 24, 1912. Price $1.50 a copy, $12.00 a year; to members and affiliates, $1.00 a copy, $7.50 a year. Changes of address must be received two weeks before they are to be effective on our mailing list. Please send old, as well as new, address.

Depositories for A.S.M.E. Transactions in the United States

BOUND copies of the complete Transactions of The American Society of Mechanical Engineers will be found in the libraries in the United States and other countries which are listed on the following pages.

Ariel Hydroelectric Development on the Lewis River in Washington
(An arch dam with a spillway thrust block and an outdoor station.)

Hydroelectric Practice in the United States

By A. C. CLOGHER,[1] NEW YORK, N. Y.

The author discusses hydroelectric development in the United States from the earliest installation up to the present time. He points out that hydroelectric plants added to large power systems in this country during the past 15 years have been constructed because they have appeared to be more economical than thermal-electric plants for adding the same number of kilowatts to the same power system, excepting the construction of hydro-electric plants in those sections of the country where hydroelectric plants can compete with thermal electric plants in producing power and energy at the load factor of the utility loads. The author also discusses the design of equipment used in the older and in the more recent hydroelectric installations. The paper includes a list of the major hydroelectric installations in the United States together with their present rating and ultimate capacity.

DESIGN practice in the United States in respect to hydroelectric developments has been influenced to a considerable extent by a number of practical factors in addition to the technical improvements which have been made in the design of the plants and the equipment contained in them.

[1] Consulting Engineer, Ebasco Services Incorporated. Mr. Clogher was graduated from Worcester Polytechnic Institute in 1905. He became associated with H. L. Cooper in the design of the Holtwood hydroelectric development and later with the engineering firm of Viele, Blackwell and Buck on the construction of the Schagticoke hydroelectric development. In 1909 he became associated with the Electric Bond and Share Company as hydraulic engineer, and later became consulting engineer of its subsidiary, which position he now holds.

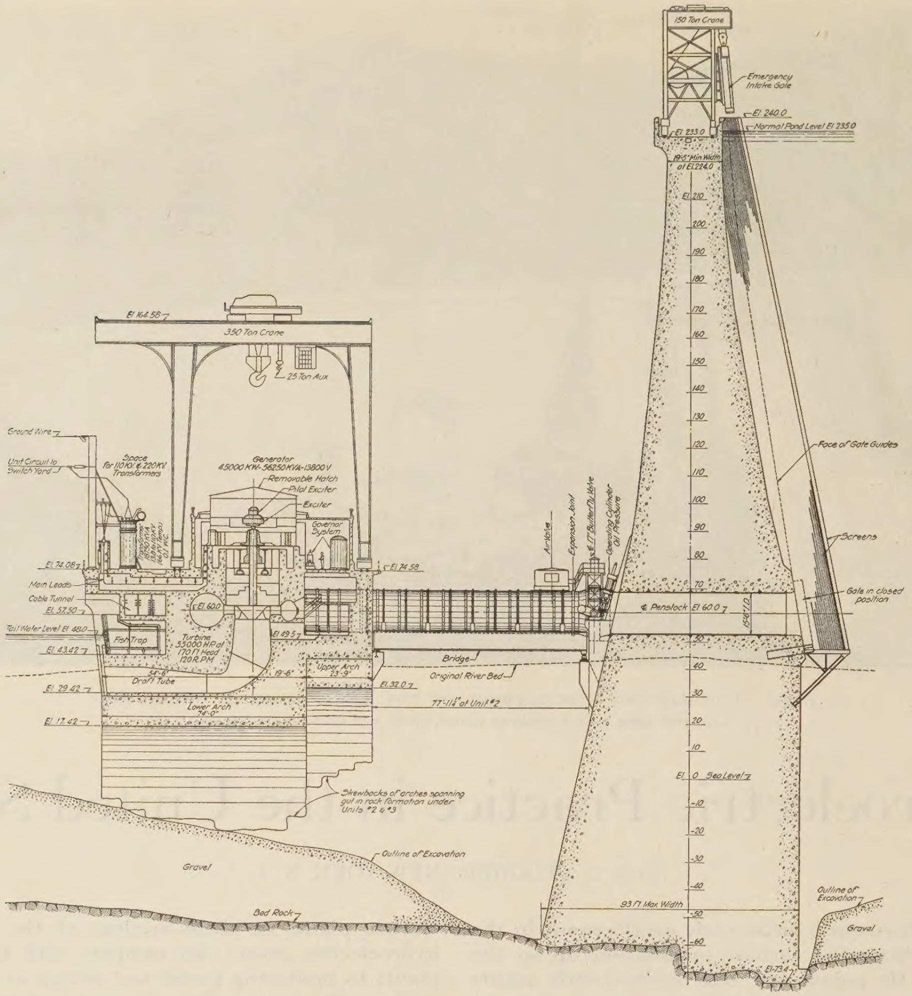
Contributed by the Hydraulic Division and presented at the Niagara Falls Meeting of The American Society of Mechanical Engineers, held at Niagara Falls, N. Y., September 17 to 19, 1936.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, N. Y., and will be accepted until April 10, 1937, for publication at a later date. Discussion received after the closing date will be returned.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

Prior to 1910 nearly all of the hydroelectric developments built served individual limited loads and areas. In some cases a single hydro plant was the sole source of power for a considerable community. The loads were small and the reliability of long-distance transmission lines had yet to be proved. The financial resources of many of these early utilities were limited. All these factors had to be taken into consideration by the designer, on top of solving the problems presented by a new kind of construction. Many of these early generating stations were small, and were without much reservoir capacity, being what is now termed "run-of-river" stations. Some of them were promoted and built as separate and independent entities, the expectation being that they would produce and sell power on a wholesale basis to others for resale to the ultimate consumer.

By 1910 the business of producing, distributing, and selling residential, commercial, and industrial electric service was fast becoming crystallized into the form which has since become the present-day public-utility operating company. The twenty years immediately following 1910 saw a great growth in load, and an equally great change in the methods used in producing and distributing power.



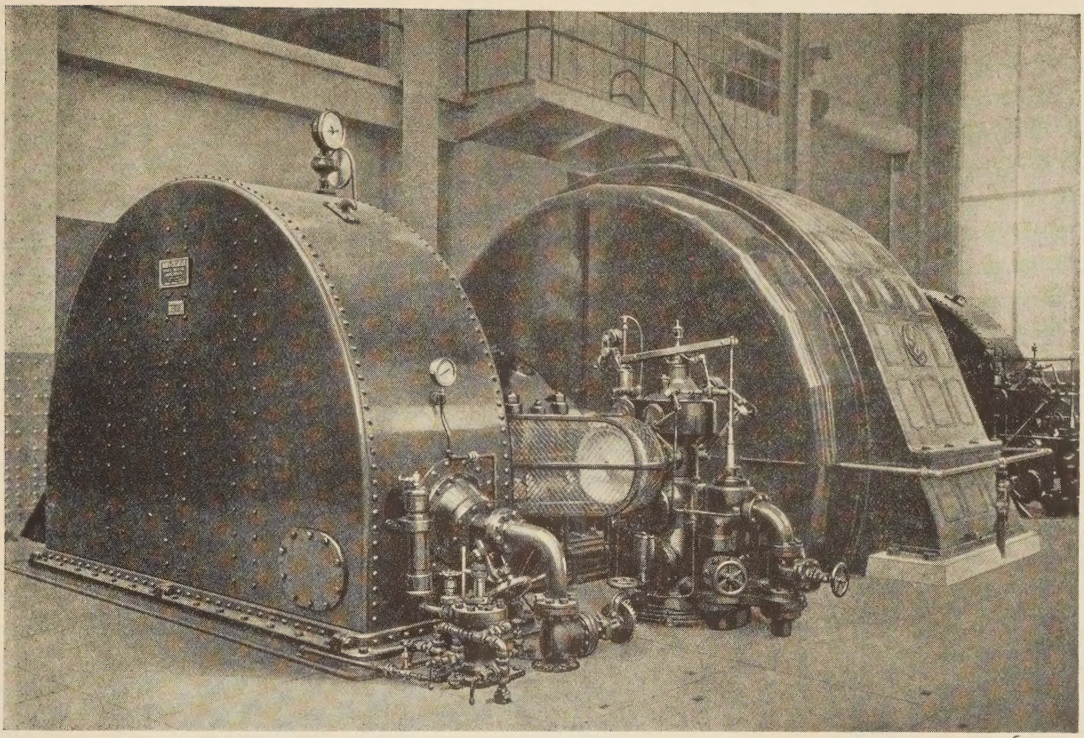
SECTION THROUGH THE DEEPEST PORTION OF THE DAM AND POWER HOUSE OF THE ARIEL DEVELOPMENT

The consolidation of operating properties was made practicable by two major savings in cost. It improved the credit of the utilities and made possible more economical financing, and substantial operating economies were secured by consolidation, especially through diversity in load and power-production sources. These changes removed some of the limitations which had been hampering the engineers, and the diversified uses of the power stations enlarged the opportunities for skill and ingenuity on the part of the power-plant designers. Almost all of the power plants constructed between 1910 and 1930 were built or caused to be built by the operating utility companies for the purpose of supplying particular sections of their own requirements for power and energy.

Thus today in the modern power system with both hydro and thermal generating stations, the run-of-river hydro plants and the thermal plants probably will be found on the base load, and the hydroelectric plants with storage capacity sufficient for peak-load operation, or with storage capacity for stream-flow regulation occupying the position on the load curve for which they are best suited. Such a power system is operated as an entity with the various generating stations treated as parts with diverse characteristics to be utilized to the best advantage to produce the most power for the least cost. The needs of the unified system has had a controlling influence on the general design, and on many of the details. It has been possible to utilize to advantage many marginal hydro sites with special characteristics which fit specific needs of the system to be served, which otherwise would have been uneconomical. The plants have been made to fit the particular load to be carried; the load has not been fitted to the power plants.

A substantial number of the early run-of-river plants are still in service. It is true that some of the earlier generating stations were not adapted for modern use, or were found to be costly to operate. In general, such obsolete stations have been scrapped. But a great many of the early power developments are still giving good service in their assigned places in the power-producing facilities of the utilities of which they are now a part. Their retention in useful and profitable service is a distinct economic gain, which would not be possible if diversified loads and generating stations had not been unified.

In the early years of this century, hydroelectric plants were generally looked upon as competitive substitutes for thermal electric plants. But after 1910, engineers began to realize that a combination of thermal and hydro generating stations had positive operating advantages, and often could produce the power required for less cost than could be done by hydro alone or by steam alone. As power systems grew in size, as larger developments became possible, and as more generating stations



THE 40,000-HP TWIN OVERHUNG IMPULSE UNIT AND GOVERNOR AT THE BALCH DEVELOPMENT ON THE KINGS RIVER IN CALIFORNIA

were interconnected, the possible combinations became more numerous, and the economy of constructing for specific and special purposes became greater. Some areas are still predominated by hydro; others are served entirely by steam. But in many others combinations are to be found with the hydros carrying the bulk of the load when water is abundant, and being shifted to peak-load service during the dry season when the steam-electric plants pick up the base load.

In the modern power system, the necessary reserves held against machine and transmission outage often are provided by extra units in the hydro stations, supported by stored water held to operate the reserve units when needed.

In another sense, the hydro and thermal plants are still in keen competition with each other. When a new hydroelectric generating station is projected, it is necessary to first prove that it will supply or make available the required power and energy for less cost than would a thermal-electric installation. In making such comparisons all the diverse factors must be considered and equated. It is often necessary, in complex power systems, to rearrange on paper the entire operating procedure including the power-plant loadings, and compare the overall results of system operation after the various types of plants are installed. In the past twenty-five years the efficiency of thermal-electric plants has increased greatly, with a consequent reduction in production costs. During the same period, in general the most desirable hydro sites have been developed. These two factors have sharpened the competition so that in most sections of the country the thermal-electric plant has an advantage for high-load-factor operation. The future for hydro developed on an economic basis in competition with other sources of power is probably in the low-load-factor and specialty field.

PLANTS HAVE FEW UNITS

The size of American operating companies and the extensive territory over which their transmission systems extend has resulted in very few of the larger systems having less than five generating stations, and in general, it might be said they have between ten and 30 generating plants tied into the same transmission network.

In addition to this diversity of generating plants, a great majority of the transmission networks are interconnected with other networks at several locations. These interconnections are valuable for maintaining service, for interchanging power and energy, and for providing for emergency service in case of breakdowns at generating stations or at other points.

These conditions account for one striking difference between American and European practice in hydroelectric power-plant general design, that is, the use of large units and of a relatively small number of them in each station. The whole station itself is looked upon as a unit of the producing facilities and this viewpoint has resulted in the construction of several one-unit stations and quite a large number with only two units as the ultimate installation. Physical limitations in the machines themselves are as a rule the reason for more than two units in a generating station.

The flexibility in loading conditions for a large number of stations under the control of one despatcher generally makes it possible to utilize one or two units very effectively. For example, a recently completed one-unit station of approximately 10,000 kw capacity is the ninth generating station and the twenty-ninth generating unit on the system of which it is a part. It can be loaded to the point of maximum efficiency for approximately 20 hr per day in the winter and for approximately 10 hr per day in the summer. Except for a relatively few hours when its maximum-peak capacity is required and a six-weeks' period annually when surplus hydro energy is available, it is operated five and one-half days per week at the maximum-efficiency point for that number of hours for which water is available. High-water sea-

sons of the year, low-load seasons, reserve capacity in hydro or thermal plants elsewhere on the same system, and interconnections with other power systems, provide the necessary reserve for maintenance and breakdowns in such a one-unit station. A list of major hydroelectric installations in the United States is given in Table 1. Articles describing some of the plants are listed in the Bibliography at the end of the paper.

Simplicity of Design

Between 1905 and 1915 there was a tendency to standardize hydroelectric plants in their general layout. An even number of units was considered preferable, so as to make a symmetrical plan centering around a central bay which contained two or more exciter units or house turbines together with other auxiliaries, including possibly a multiunit, central oil-pumping system for governors and bearings. At the entrance end there would be provided repair space and miscellaneous small rooms for storage, machine shop, and offices. A prominent feature of such a plan was the switchboard gallery, extending over the auxiliary bay in the center. An extensive electrical bay occupied the whole of the tailrace side of the superstructure (sometimes it was on the opposite side) making a space for generator busses and switch gallery, transformers, high-tension busses, and switches and special rooms for d-c exciter busses and station auxiliary busses. Such a layout was considered the ideal design for hydroelectric installations.

The very large American plants designed in recent years still contain many of the principal features of that ideal plant, due partly to conservatism, due partly to the fact that idealism is a relatively dominant factor in the design of those plants, and due partly to the excellent quality of that conception of a general plan for a large hydroelectric plant.

The competition of thermal plants, the change in service requirements, the use of marginal sites, and the "special-purpose" plants, have directed the trend of design toward simplicity, low construction cost, and low operating expense. It is no longer

TABLE 1 MAJOR HYDROELECTRIC DEVELOPMENTS[a] IN THE UNITED STATES BUILT SUBSEQUENT TO 1924 AND IN OPERATION OR UNDER CONSTRUCTION IN 1934[b] (Continued)

Development	River	State	Operating company	Ultimate horsepower	In operation or being installed: Hp	Year of initial operation	Year of completion

[a] Ultimate capacity more than 20,000 hp.
[b] Data in this table taken from Table 11 in "A Survey of Hydroelectric Developments," *Electrical Engineering*, vol. 53, 1931, p. 988 and p. 1086. (Table given on pp. 1090–1093.)

necessary to have each plant a self-contained unit, as spare equipment in other plants is available in case of breakdown.

Where simplicity is the dominant note in the design reliability must be secured by the greatest possible perfection of every detail. Electrical equipment is now so reliable that it is not necessary to provide spare exciters for the generators. American engineers are now conceiving of hydroelectric units, and in some cases of hydroelectric plants, as being only as reliable as their weakest link. The design problem, is therefore, to provide strength in every link rather than to provide extra or alternate links.

Dams

The gravity-type concrete dam with the spillway controlled by gates and located near the center of the structure, and discharging into the original river channel at the downstream toe of the dam, is a very common type of dam. Protection of the river bed rock formation was entirely neglected in the early projects but it is now almost universal practice to provide protection against the erosion which might be caused by the discharge from spillways.

The single-arch dam has been given increased attention during the past 15 years and it seems likely that this type of dam will be more widely used in the future. Improvements in design, corroborated by careful laboratory tests, new methods of precooling, closing, and grouting, together with greater certainty in the quality of our concrete masonry, have shown that the single-arch dam, in suitable locations, can effect very considerable savings in cost. Several successfully completed and operating dams of this type, equipped with gates on the spillway crest and located in the center of the arch, have demonstrated that neither favorable topography for a side channel spillway nor tunnels are necessary for the discharge of flood waters in the more ordinary sized structures.

Artificial cooling of the concrete, first successfully practiced on the Ariel arch dam in Washington, avoids any handicap to the single-arch dam on account of speed of construction.

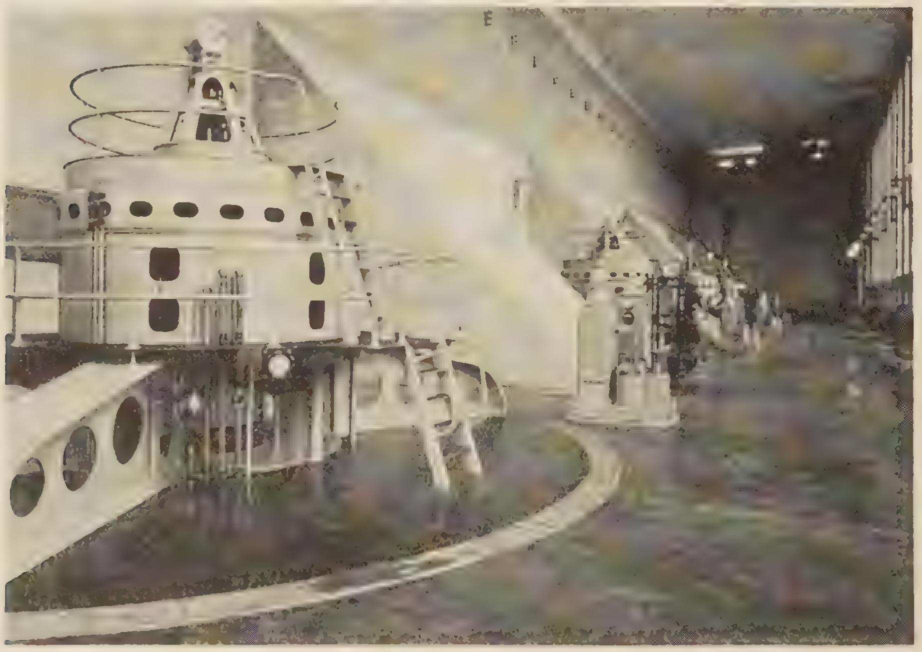
Cellular dams of reinforced concrete and multiple-arch dams have been utilized to some extent but some questionably designed structures, many poorly constructed ones, especially for severe climatic conditions and steadily decreasing costs in the production of mass concrete, have mitigated against any widespread use of cellular dams. A better understanding of the problems involved in the temperature changes in multiple-arch dams may make this type of structure more prevalent in the southern half of our country in the future.

It is almost a universal custom in this country to place gates on spillways for the purpose of increasing the storage available and in order to utilize all of the land which must be purchased to the greatest possible extent.

Intakes and Conduits

The predominance of relatively low-head plants in this country and the tendency to use very large units has necessitated a careful scrutiny of the problem of intake design. Early screening structures were built of a combination of concrete and structural steel

THE CALDERWOOD DEVELOPMENT ON THE TENNESSEE RIVER
(The arch dam is 230 ft high with a low dam below to form a stilling pool 35 ft deep.)



INTERIOR OF THE POWERHOUSE AT THE JORDAN DAM DEVELOPMENT ON THE COOSA RIVER IN ALABAMA

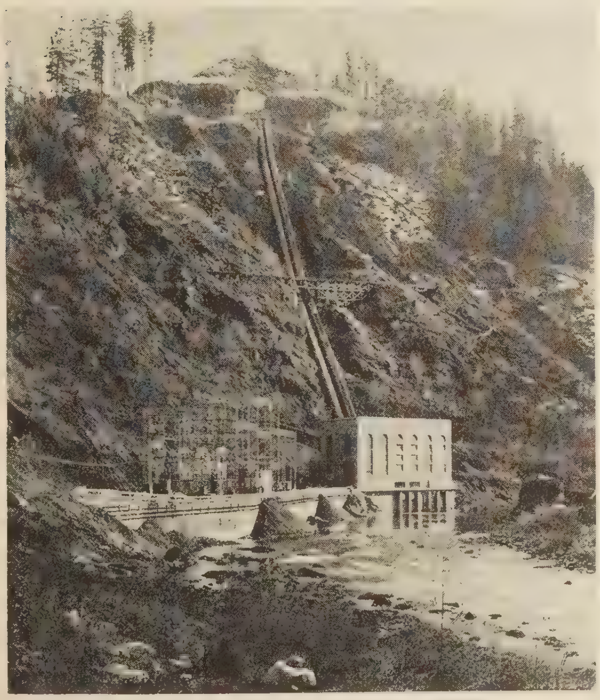
without much attention to the possible deterioration of either type of material. This shortcoming has been corrected in two ways, one, by the use of all reinforced concrete for the fixed structure, and the other by the use of all structural steel. Concrete is more expensive and presumably need never be replaced while structural steel is relatively cheap in first cost and easily replaceable when properly designed with that end in view. A splice in the vertical members at an extremely low water elevation makes it possible to replace the top or fast deteriorating section quite easily, and bronze anchor bolts and nuts make the replacement of the whole structure possible, with the aid of a diver, at some distant year of the future.

Mechanical rakes are successful and utilized where the amount of trash is appreciable. Compressed air has been found effective and is utilized extensively for lifting trash on the screens to the water surface, where it can be removed and disposed of. It is also useful in pumping warm water from the bottom of the reservoir to the surface and in this way is helpful in avoiding ice troubles around screens and at gates on the spillways.

There has been too great a tendency to design intakes on the assumption that increasing the velocity of flow was the symmetrical opposite of decreasing the velocity. Experiments with models have shown that an increase in velocity can be accomplished very quickly and that consequently elaborately long bellmouths and a multiplicity of large gates necessitated by the use of such an entrance, are not necessary and certainly are not justified by reason of any economic advantages to be obtained thereby. For medium-head plants in which the units are placed as close as possible to the downstream toe of a bulkhead wall, the reduction in the length and cross section of the conduit and the confining of the water within a steel penstock limits the uplift effect of the water and provides more weight in the upstream side of the wall.

The Outdoor-Type Morony Development on the Missouri River in Montana Showing the Low Powerhouse and Gantry Crane
(Installed with two 22,500-kw units operating at 81.8 rpm under a rated head of 82.5 ft.)

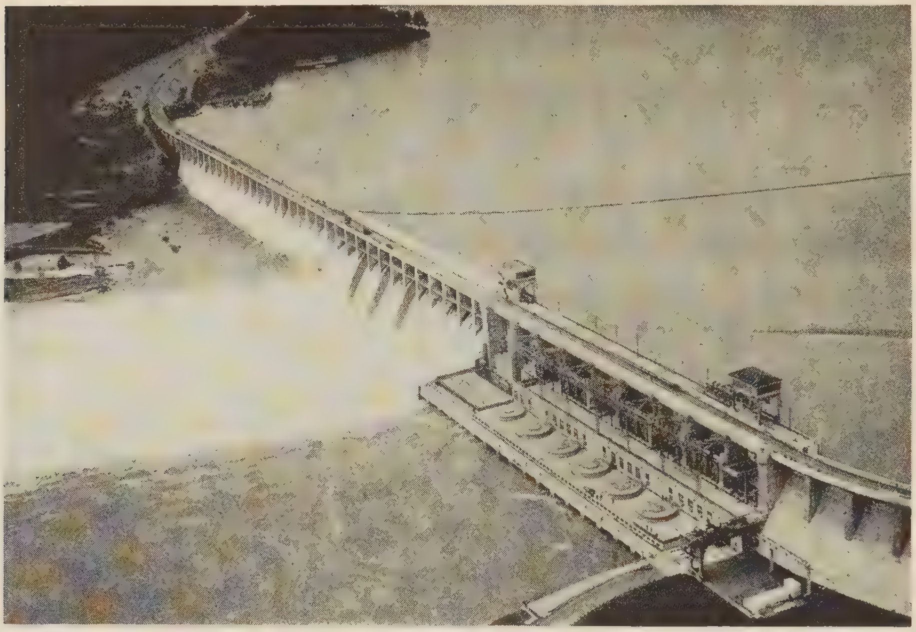


Oak Grove Development on the Clackamas River in Oregon
(Power developed by two 25,000-kw units operating at 514 rpm under a rated head of 849 ft. The highest head reaction units in the United States are located in this station.)

Canals of course continue to be the cheapest method, where favorable topography exists, for conducting water from diversion point to forebay. The use of canals, however, has been very much reduced during recent years because the low cost, permanency, freedom from operating troubles and the additional storage obtained by building a dam with power plant adjacent, have outweighed the use of canals in low- and medium-head developments, and in the case of high-head plants, because of climatic and topographic conditions which generally make the canal still more unreliable and expensive to operate. The use of canals in our hydroelectric plants during the past 15 years has been rather exceptional. They are almost invariably lined with concrete, although irrigation practice has shown that in mild climates a very thin coat of mortar shot from a gun over a wire mesh reinforcement may be more economical.

Wooden flumes have proved to be economical and effective as water conduits in many of our developments heretofore and generally these are being replaced with the same type of structure, although conditions have not been favorable in recent years for very many new projects involving wooden flumes. Canals and open flumes are at a disadvantage for low-load-factor projects unless there is storage capacity between them and the generating station.

Wood-stave pipe lines seem to be a type of structure peculiar to the United States and this type of pipe continues to be utilized where conditions are suitable for pipes up to as large as 12 to 16 ft in diameter. In most parts of the country they still continue to show a very considerable economy over pipes built of plate steel.



Osage Development on the Missouri River

(Installed with six 21,500-kw overhung units operating at 112.5 rpm under a rated head of 90 ft.)

The earlier wood-stave pipe lines were either fully buried in the ground or buried to the horizontal diameter. It was found that in most situations much more rapid decay resulted in the case of buried or partially buried wood-stave pipes. Fine tightly packed soil, which is thoroughly saturated by the leakage from the pipe itself, is favorable to long life. In most locations, however, it has been found that the best results could be obtained by supporting the pipe above ground. A great majority of the larger sized wood-stave pipe lines for hydroelectric plants constructed during the past 15 years have been so constructed. Wooden saddles have been utilized on minor installations but in the more important projects, reinforced-concrete saddles or structural-steel saddles extending almost around the bottom half of the pipe have been utilized. These saddles are placed accurately on masonry foundations, the pipe being erected in the saddles previously fastened in place.

The slight amount of leakage which is involved in continuous wood-stave pipes tends to saturate reinforced-concrete saddles and places a severe test upon the permanency of such concrete when used in climates having severe winter weather conditions.

In the case of both continuous wood-stave pipe and plate-steel pipe utilized as flow lines on almost a horizontal grade for hydroelectric plants, a considerable amount of engineering analysis and model testing has proved to be justified in order to determine the most economical design and spacing of saddles, and the stiffening necessary on the pipe. The design of saddles and stiffeners is governed by the problem of filling the pipes rather than by the load carried after the pipe is filled and under pressure.

In the use of plate-steel penstocks, riveted connections have until recent years been used in the great majority of projects. For extremely high heads, butt-welded joints have been used on the longitudinal seams with either riveted or bolted flange connections for the circumferential seams. In recent years the development of electric welding both in the shop and in the field indicates that this type of welding will be used more prevalently in the future.

Pressure tunnels have not been used extensively in this country although we have one project in which this type of conduit was used for a length of 33,000 ft and a maximum head of over 800 ft. Exceptionally favorable geologic conditions were present and the conduit has proved to be a complete success, although it was lined with only a minimum amount of unreinforced concrete. It is possible where the formation is favorable that this type of conduit will be used more in the future, particularly in view of the development of machinery for lining tunnels with concrete and greater familiarity in the use of grouting machines for tightening the structure adjacent to the conduit after the lining has been placed.

In subdividing flow lines or in taking off branch lines for different units in a power plant, it is the general practice to use wyes in these flow lines so as to present no abrupt changes in direction of flow or velocity. This is somewhat in contrast with the European custom of extending a penstock parallel to one side of the generating station and taking off a branch to each turbine by means of a tee connection.

The differential surge tank has been used in this country for over 20 years and while its adoption by engineers in this country was rather slow, it is now universally accepted as being the most economical method of taking care of the surges in long flow lines.

Penstock Valves

Gate valves designed in accordance with standard waterworks practice have proved satisfactory for moderate heads and small sizes, but as larger sizes have been required, standard valves have not proved to be adequate although satisfactory results have been obtained where the so-called follower-ring type of gate valve has been utilized. The cheapest, reliable large valve, and one which has been extensively utilized, is the pivot or butterfly valve. There has been an extensive and successful use also of the hydraulically operated needle valve. The Escher Wyss rotary-type valve has been used in this country to only a very small extent.

In the simplification of some of our plants, ecespially those where only one unit is supplied from one penstock, it has been

found practicable to omit any valve at the lower end of the penstock for heads as high as 200 ft. This simplification has proved to be quite satisfactory but necessitates the installation of a very reliable intake gate.

Switches and Transformers

In generating-station design, the practice of housing high-voltage transformers and switches has been almost entirely abandoned. It is generally the custom to design the substructure just large enough to contain the water turbine in a substantial block of masonry with a platform overhanging the tailrace providing space for the high-tension step-up transformers. In recent years even busses at generator voltage have been eliminated or have been placed out of doors so that the superstructures have been limited in size to the size of the masonry comprising the substructure. It has been found that with the auxiliary equipment simplified, practically all of it could be placed in the space around the unit made available by reason of the nature of the design of the turbine and generator.

Outdoor-Type Generating Plants

Excepting for the Hengstey II power plant in Germany and the Vargon development in Sweden, no other instance is known of European engineers adopting the plan of utilizing an outdoor crane, and thereby reducing the superstructure to that size necessary to enclose the generating units only. This arrangement was first used in this country in 1912 and has now been adopted in the case of some of our largest power plants. This scheme is no longer experimental. It has been adopted for 20 generating stations, some of them in locations where our most severe winter climate prevails and the record shows approximately 220 plant years of successful operation.

The outdoor crane has been used in this country at two thermal-electric plants and at a number of substations containing large synchronous condensers. A list of plants using outdoor cranes is given in Table 2.

It is claimed that both the cost of and time for the construction of a generating station can be saved by the use of outdoor cranes. It is believed, however, that conservatism has prevented their more general adoption in this country. It is in stations having a large number of units that the larger percentage of savings in cost can be shown for the outdoor-crane type of design.

While a number of the early hydroelectric units, especially in the larger sizes, utilized vertical shaft multirunners with direct-connected generators, horizontal-shaft units were the predominant type between 1900 and 1910, after which time the single-runner, vertical-shaft type of unit began to gain the ascendancy, a strong impetus being given to the vertical-shaft type at that time by the development of the Kingsbury thrust bearing. Since 1915, the single-runner, vertical-shaft, direct-connected generator type of unit has been almost universal for reaction-type turbines.

The vertical-shaft type of unit with three guide bearings, one on top of the turbine, one below, and one above the generator rotor, with the thrust bearing located above the upper guide bearing and supported by means of brackets on the top of the generator stator frame, with a direct-connected exciter above the thrust bearing (for speeds of 100 rpm and higher) had become practically a standard type in this country by 1920.

Umbrella-Type Generator

In 1923, a decided variation in this arrangement was introduced, which has been called the "umbrella" or "overhung" type of unit. It has been advocated and used only for units in the lower speed range and, depending on the kilowatt capacity of the generator, it is feasible to use this type up to speeds between 200 and 300 rpm.

In the umbrella-type unit, the thrust bearing is placed under the generator rotor and is supported on brackets resting on the top of the cylinder separating the turbine and the generator. The three guide bearings have been reduced to two in most cases, one being located as high up as possible and directly under the thrust bearing, the other being located on the turbine head cover. In some of the higher-speed units a relatively light bracket and guide bearing has been placed on top of the generator as well. This has been deemed desirable in cases where the speed approaches the higher range and a direct-connected exciter is mounted on top of the generator. The change in the location of the thrust bearing from above to below the generator was not new in 1923. That scheme was utilized in several of our more important stations in the early period of hydroelectric development but it had been practically abandoned by 1915.

The advantages of the umbrella type are that it reduces the guide bearings from three to two, materially shortens the span necessary for the bracket supporting the thrust bearing, and makes it possible to dismantle the generator for inspection and repairs without disturbing the thrust bearing, shaft, and turbine.

With impulse-type units, horizontal shafts are almost the universal practice. The number of impulse-type installations in important hydroelectric projects in this country during the past 15 years has been relatively small. The few large installations which have been made consist of two bearing units, the generator being mounted in the center and an impulse turbine overhung on each end of the shaft. One nozzle on each runner is the general practice.

Generator Excitation

There has been a continuing tendency toward simplification in the provisions for exciting the main units except in the very large generating stations containing a large number of units. In some of these larger plants, a-c house units provide power for driving a motor-generator exciter located close to each unit. Spare motor-generator sets are generally provided for use in case of trouble with the regular unit.

In some of the larger plants and in practically all of the smaller and least important plants, except those in which the units operate at extremely low speeds, the direct-connected exciter is the more prevalent type. It has been customary to provide some type of reserve exciter such as a motor-driven or a water-wheel-driven exciter which can be connected for use on any one of several of the main units, but on account of the fact that present-day exciter generators are among the most reliable pieces of ma-

chinery used in connection with hydroelectric-power generation, there is a tendency toward the elimination of spares and making the use of each unit entirely dependent on the availability of its particular direct-connected exciter.

In many of the slower-speed units, on account of increased cost of slow-speed exciters, motor-driven exciters are used and dependence for the starting of the station and a power supply, if the plant happens to be completely shut down, is placed on the transmission line or lines entering the station from the transmission system.

Pilot exciters are coming into use to an increasing degree with the larger machines. The inherent advantages obtained are quick-response excitation which helps to maintain system stability, the ability to reach lower stable values of field excitation for leading power-factor conditions, and the elimination of the generator field rheostat with consequent saving in space and cost.

Ventilation

In the early stages of hydroelectric development, generators were cooled simply by fans built into the machines or so arranged as to circulate air through the coils of the armature. No attempt was made to separate the incoming from the outgoing air and, in hot climates with only the thermocycle to change the air in the generating-station building itself, this often resulted in limiting the capacity of the generators. As the vertical-shaft type of unit became more popular, improvements in ventilation were gradually made by introducing air from outdoors through a duct to the underside of the generator and discharging it into the generating station where it escaped through the windows. Later on this system was improved by conducting the hot air discharged from the generators out of the generating station through a duct and in many cases the air entering the generator was passed through an air washer for the purpose of cleaning and cooling the air and increasing the generator capacity.

About ten years ago, the completely enclosed generator came into use, one in which the air is circulated alternately through the generator and through cold-water cooling coils. This method of cooling generators is utilized in the great majority of installations at the present time. It is particularly adaptable to hydroelectric units where there is generally an ample supply of sufficiently cold water to carry away the heat in a comparatively small space, and this method of cooling provides greater freedom and more space for auxiliaries directly around the unit itself than is the case when air washers and air ducts are utilized.

Generator Voltages

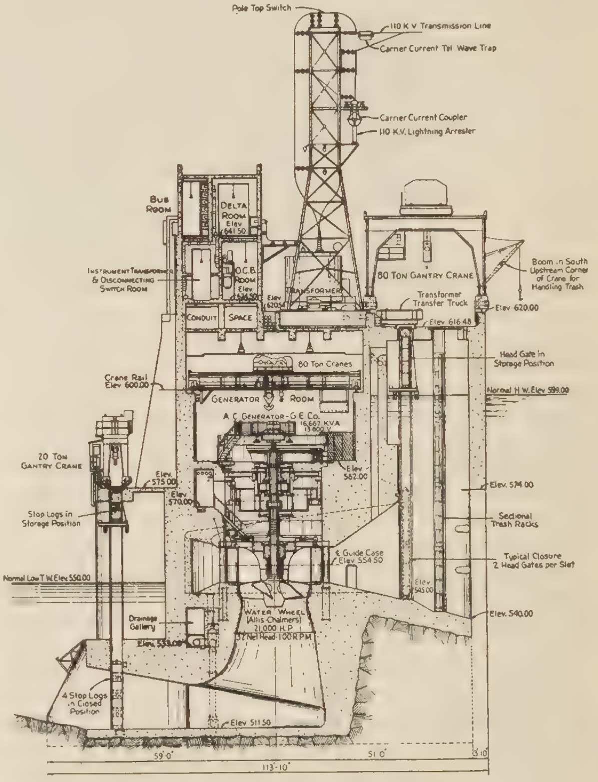
In the early stages of hydroelectric development 2300 v was the common generator voltage. This is seldom used now and 6900 v is standard for the smaller machines and 13,800 v for those of the larger sizes. The use of busses at generator voltage was quite common up to about 1920 but in stations built since that time the tendency has been to get away from this arrangement. This same tendency is apparent in the design of our thermal-electric stations as well. Many installations now provide no oil circuit breakers between the generator and the transformer which is installed as a unit with the generator. In many such cases an auxiliary house-service transformer is tied solidly on to the generator leads.

Transformers

High-voltage step-up transformers are now almost universally placed either directly against or outside the generating-station building and the unit high-voltage circuits connecting with high-voltage switches and busses are located either on the top of the generator station and dam or in a switchyard located at some distance from the generating station where a sufficiently large area of flat ground is available. This is particularly desirable when the generating station is the focus of a number of high-tension transmission lines.

Bearings

Twenty-five years ago the Kingsbury bearing greatly simplified the thrust-bearing problem by eliminating the circulation of oil, particularly at high pressure. In some of the earlier Kingsbury bearings the oil was circulated between the bearings and cooling tanks by means of exterior pumps, but the universal practice at the present time is to enclose the bearing in a bath of oil and in this oil bath to provide coils for keeping the oil cool by circulating cold water through them.



Main Unit

Rock Island Development on the Columbia River in Washington Showing a Section Through the Intake and Powerhouse

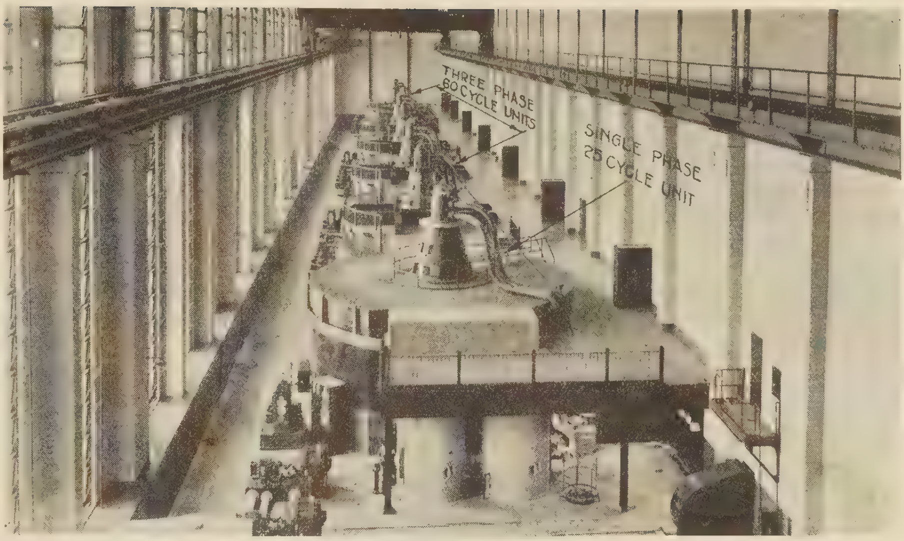
(The installation consists of four 15,000-kw propeller-type units operating at 100 rpm under a rated head of 32 ft. Provision is made for unusually high tailwater.)

Lubrication of vertical guide bearings has been simplified from elaborate central oil-pumping and cooling systems circulating oil to each bearing to one in which a small pump is made a part of the bearing and operated from the main shaft. Careful development of these pumps has improved their reliability and it is quite common to rely on one such self-contained pump for lubricating the turbine bearing and one pump for lubricating the generator bearing or both generator bearings if there are two such bearings on the unit. For the guide bearing directly above the turbine runner, water lubrication has never been abandoned, however, and many units with that type of lubrication are in successful operation.

The development of the umbrella-type unit, having only two guide bearings, of necessity requires very accurate alignment of the lower bearing. The difficulties involved in connection with

the design and operation of the oil-lubricated bearing on the top of the propeller or Kaplan type of runner have revived interest in water-lubricated bearings and the lining of these bearings with rubber instead of lignum vitae is indicated for many future installations.

Turbine and generator shafts are generally made by the respective manufacturer of the machines and are joined by means of a forged flanged coupling. Some operating companies have insisted on the use of one piece of shafting for the whole unit or on sufficient crane clearance and other clearances large enough so that the flanged coupling need never be dismantled after its first erection.



Powerhouse of the Safe Harbor Development on the Susquehanna River in Pennsylvania

(Installed with six 28,000-kw units. The rated head is 55 ft and the speed of 60-cycle units is 109.1 rpm while the speed of the 25-cycle unit is 100 rpm.)

Turbine Types

The Francis type of runner has always been the predominant one in this country because of the relative scarcity of sites suitable for impulse machines. This type of runner has been utilized in quite a number of developments for heads over 600 ft, the highest being an installation under a head of 930 ft. Reaction turbines have been feasible and economical for these higher heads because of the large size of the units involved.

Propeller and the Kaplan movable-vane runners have come into use gradually during the last 15 years, and the installations have gradually increased in capacity and the amount of head involved. In the future, we shall probably see very few installations of Francis turbines for heads under 75 ft since the propeller-type runner is now very generally accepted for low-head installations. One installation of automatically self-adjusting runner blades is in operation but this type of blade control is so new that the opportunity has not yet presented itself for the adoption of many installations of this type.

Scroll cases for the passageways leading to and around the turbine are constructed of materials dependent on the size of the unit and head under which it operates. For extremely low heads, reinforced-concrete scroll cases or open flumes are used. For high heads, cast iron is used for small units and cast-steel, riveted, or welded steel plates are used for the larger units under the higher heads. In many installations the top half of the plate-steel scroll case is not buried tightly into the concrete comprising the substructure of the generating station. Instead the top half of the casing is covered with a crushable material such as celotex, which, by reason of its easy compressibility allows the turbine casing to "breathe" without distorting or overstressing the concrete surrounding the casing.

Draft-tube design has been the subject of much study and laboratory testing. The elbow type of draft tube is the one most widely used, although the vertical tube with variations of a concentric cone of metal and concrete directly under the runner has been used to a considerable extent. The central cone extending all the way up through the draft tube to the bottom of the central part of the runner is now the general practice when this type is used.

In many installations it has been found that the efficiency of the unit is considerably increased at the lower gate openings and that smoother operation and avoidance of water hammer in the draft tube is secured by the admission of air at the top of the runner and draft tube. The amount entering is adjusted automatically by means of levers connected to the gate mechanism and decreases as the gate opening increases, usually becoming zero at about 40 per cent gate opening.

Turbine runners are made of cast iron, cast steel, and various types of bronzes depending on size, capacity, and quality of the water. Construction of runners of stainless steel has been seriously proposed but not as yet put into practice.

Observation of pitting on a great many turbine runners and laboratory tests has shown engineers the importance of cavitation in turbine maintenance. As a result of these studies turbines are now generally set as low as possible relative to tailwater.

Small turbine runners for many years have been made of steel plates pressed accurately into shape and fused to a cast-iron hub and outside ring by casting the iron directly against the plates. This method has been used principally in small installations and has not been very generally adopted in American hydroelectric practice. However, it is being revived now on account of the perfection and reliability of electric welding. The modern method is to cast the hub and outside ring of steel separately and by means of electric welding assemble these cast-steel parts with the pressed-steel plates.

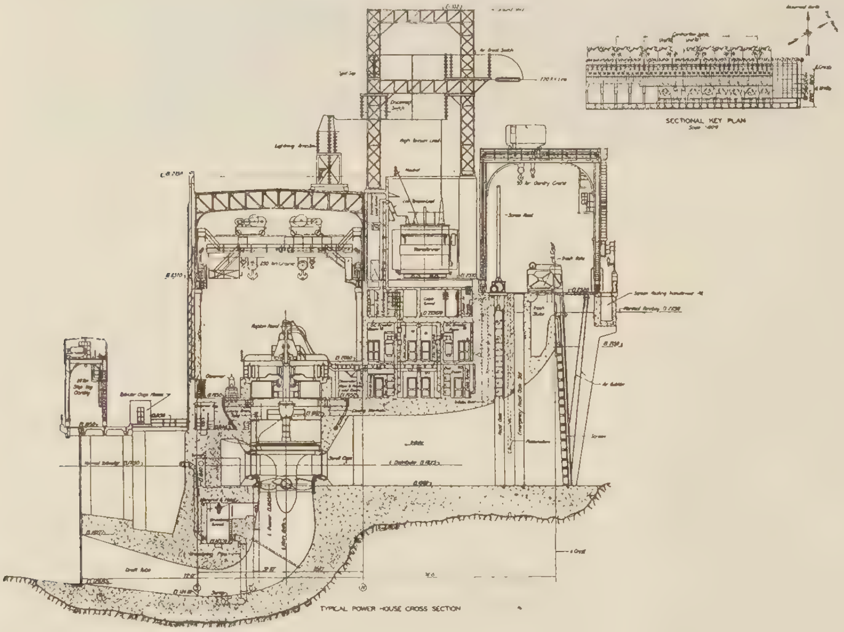
Governors

The hydraulic oil governor actuated by flyballs has been in use almost from the inception of hydroelectric development. It is still used exclusively for governing hydroelectric units, although, of course, it has been improved upon and enlarged in size from year to year. In general, it might be said that most American operators of hydroelectric stations have not insisted upon extreme sensitivity and quick action in hydraulic governors. Many of the power systems have had some steam turbines operating as part of the generating capacity and most of the operators in the past have been content to allow the steam turbines to do the governing, the gate opening of the hydraulic units being set by means of a governor stop or resulting from sluggishness because of purposeful adjustment or neglect. This method of operating has been satisfactory in many of the power systems in the past, but with the extensive interconnections which have come into

use in the past fifteen years, the demand for synchronization and operating interconnections over increasingly large areas of the United States and the demand for better speed regulation, have made it necessary to provide well maintained hydraulic governors on all important units. It is now quite generally appreciated that any governor operated against a stop eliminates just so much governing capacity from the system and changes the governor into practically nothing more than a safety device against runaway.

Automatic Control

Automatic control of the pilot-valve setting is now a definitely accomplished fact both for controlling speed and controlling load. Many of these automatic installations are in use.



Section Through the Powerhouse at Safe Harbor Showing the Kaplan-Type Unit

It has been customary for many years to provide a governor switch on the control board so that the motor used for changing the length of the pilot-valve stem could be actuated by an operator observing either speed or load on the instrument board. The automatic-control apparatus referred to previously does this automatically either for one unit or for a group of units and can be arranged to open and close the gates on a group of units so as to secure the maximum efficiency from the group. This apparatus is applicable to thermal-electric units as well as to hydroelectric units and is utilized on one or more plants of practically all of the areas of the country now tied together and operating in synchronism.

This apparatus does nothing new and does only what can be accomplished by well-trained operators giving continual attention to the speed or load, whichever it is desired to control in any particular station or for any particular unit. It has the advantage, however, that it gives continual attention to the problem of adjusting the governors to secure the speed and load required and sends an impulse to the governor to accomplish this every 2 sec so that accuracy of results has been secured which has never been possible by means of human control. The use of this automatic apparatus makes possible the greater interconnection and synchronous operation of large transmission networks and in many cases makes it possible to transmit power over long lines of small capacity in greater quantities and with much greater reliability and protection against overloading of switches than it has been possible to accomplish heretofore.

Switchboards

The extensive switchboard gallery, one of the important features of the standard plan for hydroelectric stations, referred to previously, is entirely outmoded. It is now called the control room and may be located in almost any part of the building or even outside in a separate building. In some instances, the heritage of the switchboard gallery still compels its location where windows may be provided so that the operators can look into or down onto the generator room. Many designers and operators do not consider it essential that any other part of the plant be visible from the control room but in small stations, it is preferably located for convenient supervision of all operating machinery.

The control room is constructed so as to be as quiet as may be practicable by carefully soundproofing it against the noise created by the main units and auxiliary machinery. It is separately heated, cooled, and ventilated so as to secure more uniform and comfortable atmospheric conditions than is possible in the main part of the station itself.

Increasing attention is being given to the ventilation of all parts of the generating stations, particularly with a view toward securing cleanliness. It has long been the custom to screen all windows and doors but the tendency today is to design generating stations so that all windows and doors can be kept closed all the year round, and the station ventilated mechanically with perhaps a very slightly higher pressure in the building than outside. This feature is especially desirable in semiarid parts of the country where there is a considerable amount of dust in the atmosphere.

Architectural and structural details are generally designed strictly from a utilitarian point of view, factory standards being used in most cases. In many of the larger plants, careful attention has been given to securing a pleasing architectural effect in the superstructure although as a general rule it might be said that American practice places much less emphasis on architectural expression in generating-station buildings than does European practice.

Automatic operation of small hydroelectric plants has presented a fascinating problem to designing engineers for the past 20 years. Several automatic stations are in successful operation, one of them containing a unit of 12,000-kw capacity. Very little progress is being made toward a wider adoption of the automatic plant because of its high cost for extremely small plants and because of the fact that for the larger plants, it has been found that the advantage of not having an attendant is offset by the reluctance of the operators in charge of the property to lock the plant and leave it without a watchman. This has resulted in a compromise in some instances and in so designing the plants that only a very small operating force is required. Where a station is located within a very few miles of another op-

erating station, control cables have been utilized for operating the auxiliary station and controlling it to a limited extent from the control room of the larger station. Many small and unimportant stations are equipped for operation without an attendant under ordinary conditions. An attendant visits the plant once each day and must be present to start and synchronize it if it should automatically shut itself down.

Hydroelectric Practice in Canada

By T. H. Hogg,[1] Toronto, Ont.

The author discusses the advances in hydroelectric practice that have been made during the last twelve years, sketching first the revolutionary changes which had taken place in the earlier years of the century. An account of the rapid growth in hydraulic development in Canada, which reached a total of 7,909,000 horsepower by the end of 1935, is amplified by tabular and graphic records of the energy generated in central electric stations in the country.

A survey is then made of the principal changes made in various elements of hydroelectric developments. There has been a great advance in the use of propeller-type units, and their field has been extended in capacity and to higher heads than was the case in 1924, but no radical advance can be recorded in connection with Francis turbines of moderate specific speed. Reference is made to improvements in welding practice in connection with the renewal of pitted parts of turbine runners and in electric drives for governor flyball heads.

A survey is then made of electrical equipment, in which it is seen that, while advances in generator, transformer, connections, and switching practice are comparable to those experienced in the purely hydraulic portions of the installation, the most striking advances have been made in control and automatic-relay protection.

THE WRITER of a paper presented at the World Power Conference at London in 1924, dealing with water-power development in Canada, made this assertion: "It may be stated, with a fair degree of assurance, that the future holds no prospect of revolutionary advances in the art such as have taken place in the last twenty years." That period had seen a gradual increase in unit capacity of turbines, and improvement in their efficiency, an extension in realization of high efficiency over a greater percentage of the full capacity of the unit, perfection of the means of supporting revolving weights, and development of effective means of controlling long water columns.

[1] Chief Hydraulic Engineer of the Hydro-Electric Power Commission of Ontario. Dr. Hogg was graduated from the University of Toronto in 1908 with the degree of B.A.Sc. In 1914 he received the degree of C.E. and in 1927 the honorary degree of doctor of engineering. Before attending the University—from 1902 to 1904—he was on the engineering staff of the Ontario Power Company. His vacations during his University course were spent with the Niagara, Lockport, and Ontario Power Company on high-tension transmission-line construction. After graduation, he remained at the University for a short time, and in 1909 returned to the Ontario Power Company as assistant designing engineer, and was engaged also on the preliminary surveys and as superintendent of construction of the Salmon River plant at Pulaski, N. Y. Dr. Hogg was editor of *The Canadian Engineer* in 1911 and 1912. He became assistant hydraulic engineer of the Hydro-Electric Power Commission in 1913, and chief hydraulic engineer in 1924. He has had charge of the hydraulic design and construction of a score of the water-power projects of the organization, having a total capacity of over 750,000 horsepower.

Contributed by the Hydraulic Division and presented at a meeting of The American Society of Mechanical Engineers, held at Niagara Falls, N. Y., September 17 to 19, 1936.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until April 10, 1937, for publication at a later date. Discussion received after the closing date will be returned.

Reference was made to the position at that time of the propeller-type runner, undoubtedly a revolutionary advance in water-power development, which was, in 1924, just beginning to find its place. European and American practice had diverged somewhat in the development and application of this type of equipment, which is referred to later.

A field inviting investigation at that time was the cause and nature of pitting of turbine runners. The extent to which this proceeded in comparatively brief periods in many installations and the perfect freedom from it in others presented problems of great scientific and economic interest. Decided advances have been made toward a solution of the problems presented by the phenomenon of pitting.

Reviewing changes that have taken place since 1924, we find improvements have been made in governing equipment, in draft-tube design and in simplification of the layout of the hydraulic plant, but, in general, it may be said that the prediction of the improbability of revolutionary advances in the art, in so far as hydraulic plant is concerned, has been confirmed.

This is not true, however, in the broader field of hydroelectric practice. In generation, transformation, and transmission of electric power, notable changes have taken place. It is significant, however, that these changes do not apply so strikingly to generating and transforming equipment as to switching, control, and protective equipment. True, there have been advance in generator design and changes in practice regarding transformer equipment, but these are comparable to the advances made in the turbine, draft tube, and plant layout.

Statistical

In common with many other countries, Canada has experienced a rapid growth in water-power development. Developed water power, which at the beginning of the century totaled less than a quarter of a million hp, through a fairly rapid growth reached a total of 3,590,000 hp by 1924. The rate of growth thereafter for eight years was at the extremely rapid rate of 440,000 hp per year, so that the total developed power exceeded 6,125,000 hp at the end of 1930. It was hardly to be expected that the rapid growth which took place under the impetus of the business expansion subsequent to 1924 would continue, but, in spite of the adverse economic conditions of recent years, there has been a great increase in developed power, until at the end of 1935 it amounted to 7,909,000 hp.

It is quite true that a portion of the increase since 1930 is accounted for by the completion of developments planned in the years preceding 1930. In view of this, a more significant gage of the growth of the industry is provided by the number of kilowatts generated by central electric stations. It must be kept in mind that central electric stations include only those electric stations which generate power for distribution, and therefore do not include hydraulic and hydroelectric stations generating power for specific industrial establishments. As ninety-eight per cent of the output of central electric stations in Canada is generated in hydroelectric plants, and as the great majority of hydraulic plants are included in central stations, the energy generated in central stations year by year is a very reasonable gage of the growth in importance of the hydroelectric industry. The output of central electric stations in Canada amounted to 9,315,277,000 kwhr in 1924, and to 18,093,802,000 in 1929, after which a decline took place until 1932, when the output amounted to 16,052,057,000; but a subsequent steady increase carried

it to 23,410,000,000 kwhr in 1935. Developed hydraulic horsepower and output of central electric stations year by year since 1924 are shown in Fig. 1.

Power Supply for Mining Industries

An outstanding problem in hydroelectric-power generation is the growth in amount of and special provisions for meeting requirements of mining and related industries. To appreciate the

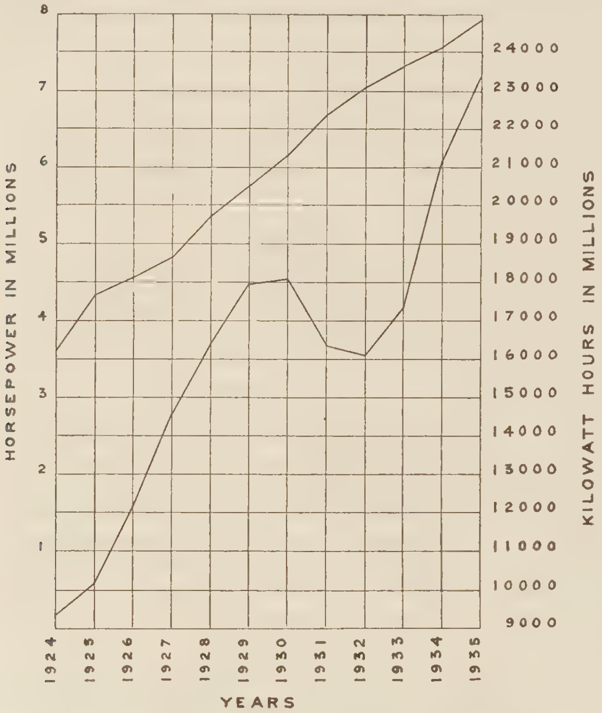

Fig. 1 Installed Hydraulic Horsepower and Energy Generated in Central Electric Stations, 1924–1935

significance of this, it is necessary to consider recent developments in mining in the Dominion.

The remarkable growth of the industry is shown by a consideration of the value of mineral production, which fifty years ago had a value of only $10,200,000, but has grown in recent years as indicated by the following tabulation: 1896, $22,474,256; 1906, $79,286,697; 1916, $177,201,534; 1926, $240,437,123; 1935, $310,162,455.

The value of production was as high in 1929 as in 1935, after which there was a slight decline, from which the industry has now recovered. In considering these figures it must be kept in mind that, while gold has risen in price, nickel has remained stationary, and all other products, metallic and nonmetallic, bring lower prices than the record prices of 1929. Copper, lead, and zinc are now selling at very low prices, lead and zinc remaining close to their minimum value. The present high production thus indicates a greatly increased gross tonnage from the mines, a greater use of power, and wider employment of machinery.

To meet the power requirements of the industry, numerous isolated developments have been necessitated by mines located far from existing sources of power supply and at points to which transportation of equipment is difficult and costly. This latter feature is not new in the mining industry, but in Ontario and Quebec, lacking as they do coal deposits, it precludes the use of fuel-produced power for mining and milling operations. Diesel power is utilized in some places in these provinces, and for preliminary operations in a new field local fuel is used, but one of the chief concerns of the mine manager now is to locate a dependable source of electric power. Probably ninety per cent of the mines in Ontario and Quebec use electric power for all purposes. Furthermore, electric equipment is used more extensively for domestic purposes in the communities in the mining districts than in other parts of these provinces.

Hydraulic Turbines

The assertion in 1924, referred to at the beginning of the paper, that we had at that time probably reached the ultimate in efficiency of Francis-type turbine runners, has been confirmed. No claims have been made for greater efficiency than was obtained at that time in a number of notable developments in Canada and elsewhere. In March, 1925, extensive and careful tests were made on unit No. 7 at the Queenston development at Niagara Falls. This unit has a rated capacity of 58,000 horsepower under a head of 294 ft, and a specific speed of 38. The turbine efficiency realized is believed to be as high as, or higher than, has been obtained in any other installation, and, what is more important from an operating standpoint, unusually high efficiency was realized over a very great range of output. The maximum turbine efficiency was 93.8 per cent, and the efficiency was greater than 90 per cent for 48 per cent of the range in capacity of the turbine.

The Abitibi Canyon development is fairly comparable with the Queenston development and, in so far as the layout and size of the units are concerned, is quite similar to it. The turbines are rated at 66,000 hp under a head of 237 ft, and have a specific speed of 41.5. Tests were made on four of the units at this development in January, 1936, by the same method as was used at Queenston. The maximum turbine efficiency realized was 93.6 per cent, nearly the same as at Queenston, and the range of high efficiency was also practically the same.

Thus, over a period of eleven years no improvement is observed in the efficiency results for large Francis-type runners of moderate specific speed, mainly because the utimate had been so closely approximated at the beginning of that period. Today's turbine, however, is in many respects a better machine, due to improvements in mechanical design and manufacturing methods. One illustration of this may be cited. In two installations of large size in which turbine gate leakage was measured, this amounted to less than 0.3 per cent of full gate discharge in the one case, and less than 0.1 per cent in the other case. Formerly, a turbine gate leakage of one per cent was not considered excessive.

Turbine practice has advanced, however, in the use of high-specific-speed runners, particularly in the extension of the application of these to higher powers and to higher heads than was the case ten years ago. Reference has been made from time to time in technical publications to the difference in European and American practice in the use of the high-speed runner. In Europe, few installations use the fixed-blade propeller-type runner, the field being practically monopolized by the Kaplan runner. In the United States, while the fixed-blade runner is used more frequently, there are also many Kaplan runners in service, some of very large size. But in Canada the field is almost entirely taken up by the fixed-blade runner. A few Kaplan runners are used, but these are of small size.

If one is to search for the reason for this preference for the fixed-blade runner in Canada, in spite of its inferiority to the Kaplan runner in maintenance of high efficiency over a great range of capacity, he will find several explanations. The fixed-blade runner presumably is more rugged than the Kaplan runner, as the latter has numerous parts moving relatively to each other. Moreover, the fixed-blade runner usually has as high maximum

efficiency as the Kaplan runner and in some instances higher. If, then, the lower efficiency of the fixed-blade runner at part loads is not a detriment, its mechanical advantages and high maximum efficiency may prompt its choice. As most of the installations in Canada form parts of large systems, it is often quite feasible to operate individual units always at high efficiency, the plant load being varied, as a unit is taken from or put on the line, by such amounts that all units operating do so at high efficiency. The operation of the Chats Falls plant on the Ottawa River illustrates what may be done in this regard. This plant, operating in the Niagara System of the Hydro-Electric Power Commission, is equipped with fixed-blade runners rated at 28,000 hp under a head of 53 ft at 125 rpm. A study of actual operating results at this plant over several periods, each one week in length, showed an overall plant efficiency as high as 83 per cent. Manifestly, the turbines were operated at all times close to the point of maximum turbine efficiency to obtain so high a result as this for the whole plant.

In other instances in which high-speed runners have been used, the governing condition has not been that of high efficiency, but rather of reliability. The single unit in the Ear Falls plant on the English River in Ontario supplies mining load, and has been called upon for continuous service since it went into operation in December, 1929. In the intervening six years, the unit has been shut down only four times, for a few hours each time, for inspection and cleaning.

Welding of Turbine Runners

Considerable progress has been made in the last ten years in the art of welding, in connection with the restoration of pitted parts of turbines. The corrosion and erosion of runner blades, throat rings, seal rings, and draft-tube sections have been experienced on high-powered as well as on high-speed turbines, and this has, in many cases, proceeded to such an extent that replacement at considerable expense has been necessary. However, through careful investigation along scientific lines by experts, welding processes now make it possible to save affected parts and restore them to efficient operating condition. Thus, for low maintenance expenditure, costly machines can be restored, instead of being replaced, and kept in service with little outage.

Cast steel and forged steel can be welded with little difficulty and, when rust-resisting materials have been applied, on turbine parts where pitting due to cavitation is unavoidable, surfaces treated in this manner stand up satisfactorily in service.

Successful maintenance work is now carried out on cast-iron runners and cast-iron throat rings with a welding process which can easily be used while such parts are assembled with the whole machine. Pitted cast-iron parts are now filled with monel metal, where previously a cheaper grade of welding steel was used. Several years of experience have proved that monel metal is a good substitute to build up corroded parts on turbines.

Welding practice in connection with maintenance of hydraulic turbines is still in a state of flux, and new processes having certain advantages or special fields of application are frequently being proposed and used. Among these might be mentioned the metal-spraying process and atomic-hydrogen process. Naturally, the product of any of these new methods, although giving promise of success, must be subjected to a service test before the method may be accepted as worthy of approval.

Governors

Mechanical drives for governor flyballs have been almost entirely superseded by electric drives. The latter, as at first installed, were not free from defects and disadvantages; in fact, various devices were proposed and used to overcome the defects and assure greater reliability.

A separate set of transformers, connected to the generator leads supplying power directly to the governor drive, gives direct connection between the unit and the governing mechanism, even when interruption occurs which separates the unit from the system. This type of drive is advantageous with high-speed flyballs, and finds frequent application at the present time.

A further advance was made by the addition of slip rings on the pilot exciter when available, from which a power supply was drawn for the governor drive. This method, although possessing advantages over those preceding it, was affected by disturbances in the main electrical system which were not related to the speed changes in the unit which the governing system is designed to control.

Apparently a power supply, quite independent of the main system, is desirable. The necessity for this prompted the development of a permanent-magnet generator, directly connected to the main-generator shaft, but independent of the main electrical system. The governor flyballs, being driven by power from this separate generating unit, are affected only by speed changes in the main-generator shaft, and tend to operate the governor mechanism only as the speed of the unit departs from normal. Satisfactory results are being experienced in an installation of this type, replacing the earlier pilot exciter drive at the Alexander development.

Generators

The use of rolled sections, instead of castings, in the fabrication of the frame and rotor of hydroelectric generators has become virtually standard practice. Improvement in welding technique and the development in rolled shapes have resulted in reduced weights, while the umbrella type of unit has tended to reduce powerhouse superstructure volume.

A tendency to reduce the size of the powerhouse superstructure is noted in several plants where the upstream wall is moved in much closer to the units than in the case of, say, the Queenston development. This tendency is seen in the Alexander and Chats Falls developments in Ontario and the Rapide Blanc and La Gabelle plants in Quebec.

Beyond this, improvements in generator designs are noted mainly in details and in the excitation system; improved insulation methods to prevent coil movement in slots under varying operating temperatures; and bracing windings more securely to withstand short-circuit stresses.

The excitation system of large generators has undergone radical changes in the last ten years. The growth of interconnections and the generally longer transmission systems carrying large and important blocks of power have resulted in stability of operation becoming an important problem. One of the first measures adopted to improve stability was the so-called "high-speed" or "rapid-response" excitation system coupled with low values of armature reactance. While other measures are now considered of greater benefit in the relief of the problem, notably the extremely rapid clearance of faults, the generator excitation system quite commonly includes a pilot-exciter and high-speed voltage regulator.

The tendency to increase generator voltages noted in other countries is not so marked in Canada, partly because only a relatively small number of new developments have been undertaken in recent years and partly because hydroelectric development in Canada almost invariably involves more or less long-distance transmission. When a step-up transformation is involved in any case, there is not the urge to increase generator voltages as is the case when generated-voltage distribution is involved.

The grounding of generator neutrals is a live subject in present-day practice. In a number of cases, where distribution at genera-

tor voltage is not present, generators are being operated with ungrounded neutrals. Damage occasioned by ground faults is thereby minimized, with no apparent countervailing disadvantages. Where distribution at generator voltage is present, the protection of the windings against lightning damage is receiving more attention.

Transformers

The principal trends in transformer design may be traced to the knowledge gained in recent years, as a result of extensive research in the field and in the laboratory in the problems of lightning protection, so that equipment as now designed is virtually lightningproof. The shielded transformer and the so-called "surge-proof" unit are products of this development.

As in the case of generators, refinements in design of transformers are being dictated by operating experience. The oil-insulated water-cooled unit continues to be used most frequently in hydroelectric installations, though the self-cooled unit supplemented in some cases by air blast finds favor where temperatures below —40 F are likely to be experienced. The forced-oil-cooling system is practically unknown in Canadian practice.

Single-phase units are by far the most common, though several installations of three-phase units have been made where economical physical dimensions have apparently been the only limit to capacity.

Application of tap-changing devices has become almost universal practice. In the majority of cases these devices operate only with the transformer deenergized, but "on-load" tap-changing equipment has been developed to the point where standard equipment can be offered to meet almost any problem.

Connections and Switching

The present tendency in station connections and switching facilities is definitely toward simplification and the elimination of duplication, as contrasted with the earlier double-bus and other more complicated arrangements.

This trend was no doubt initiated as development of more remote sites made necessary higher transmission voltages, and, consequently, more expensive switching equipment. The generally smaller number of generating units per plant, the lesser need to provide emergency connections for single generating units as systems expand, and the increasing cost of switching equipment as vastly increased circuit-interrupting speeds are demanded by modern interconnections, are all factors tending to maintain this trend.

Allied with this simplification of connections, however, has been an expansion of the automatic relay protection afforded the component parts of the electrical equipment. Generator-differential or split-phase protection, bus-differential, and transformer-differential are among the types of protection applied.

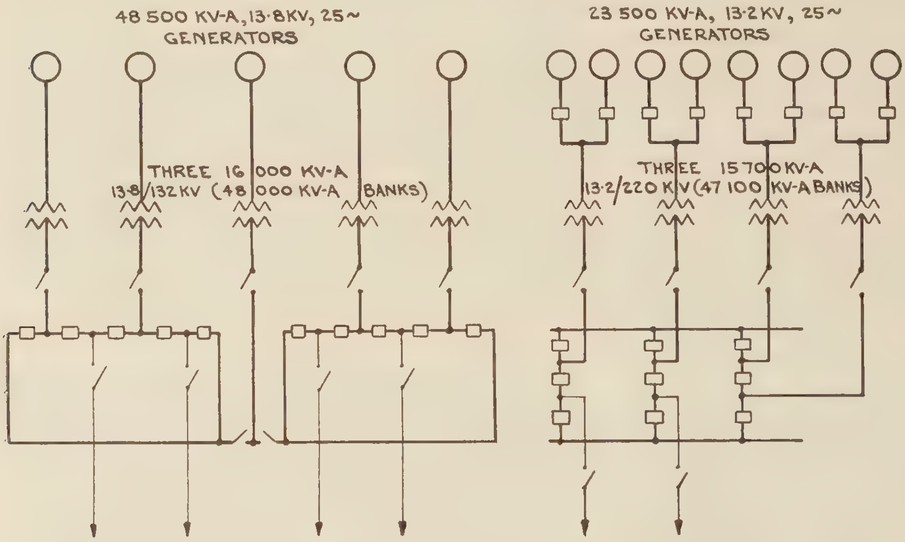

Fig. 2 Main Electrical Connections of the Abitibi Canyon Plant (Left) and the Chats Falls Plant (Right)

In many plants, for example, at Chats Falls, Beauharnois, and Abitibi Canyon, one or more generators and an associated transformer bank of the same total capacity are treated as a unit. Generator breakers, if used at all, are provided only between the unit and the transformer bank, while the high-voltage breaker arrangement may be of the ring or 1.5-type, both of which are shown in Fig. 2.

In the case of the Alexander development, a line diagram of which is shown in Fig. 3, high-tension oil circuit breakers are entirely eliminated. The transformer-bank capacity is arranged to equal that of one transmission line and forms an integral part thereof. This capacity must, however, be greater than that of the generating units connected to it, as, when a transmission line trips out, the station output must pass through the remaining lines and banks. The cost of this excess transformer capacity must of necessity be weighed against the saving in high-voltage switching equipment.

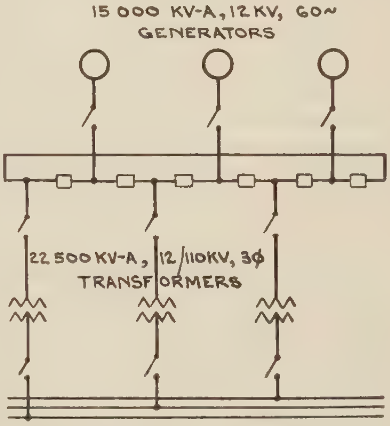

Fig. 3 Main Electrical Connections of the Alexander Development

When generator voltage switching equipment is used, the metal-clad type has found general favor, due to its compactness and its freedom from interference and outage. Such switching equipment is invariably installed within the generating station, as the space requirements are small, though transformers and high-voltage switching equipment have been usually placed outdoors.

FIG. 4 ABITIBI CANYON DEVELOPMENT, ABITIBI RIVER, ONTARIO
(Interior of generating station showing units Nos. 1 to 4.)

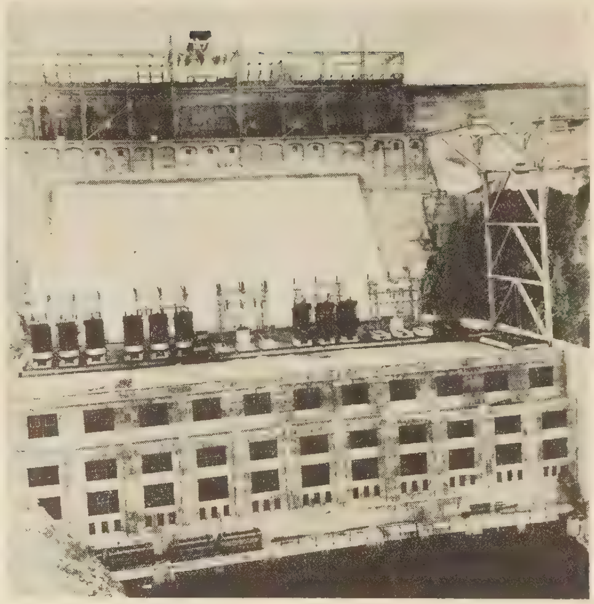

FIG. 5 ABITIBI CANYON DEVELOPMENT
(North face of powerhouse and dam.

The developments in oil circuit breakers in all voltage classes have been toward higher speeds of operation. These developments originate in various means of controlling the behavior of the arc, and much progress has been made in breakers rated at 60,000 volts and over. Standard equipment in these voltage classes is rated to clear the circuit in 8 to 10 cycles on a 60-cycle system, while special high-speed equipment is available operating in 3 to 4 cycles.

Undoubtedly the trend away from massive oil-filled circuit breakers, so noticeable in European practice, is making itself felt in Canada. Up to the present, however, no noteworthy installations of apparatus incorporating radically new principles have been made. The tendency to curtail sharply the use of high-voltage oil circuit breakers has, however, been largely responsible for a considerable improvement in the design and construction of no-load disconnecting and air-break switches. Such switches are quite frequently used to break transformer-bank exciting current and the charging current of up to fifty miles of 132-kv, 25-cycle lines, applications where, previously, oil-filled switches would have been considered almost essential. They are also successfully operating outdoors in temperatures ranging as low as —60 F.

CONTROL AND AUTOMATIC RELAY PROTECTION

The recent developments in miniature-type control switching and switchboard apparatus have brought about a radical change in the size and general design of all electrical control rooms. A compact main control board is provided, upon which are mounted miniature switches and the essential operating instruments. Control is by means of 24- to 48-volt control circuits to subcontrol panels located adjacent to the main apparatus. Graphic instruments, relays, and other equipment are mounted on these subpanels.

This design reduces the space occupied by the essential features of the control system, thus greatly facilitating plant operation and reducing costs. As an example, the control room of the Chats Falls development, designed in 1930 to provide for the ultimate installation of ten units, occupies a space of 18 × 40 ft, the main control board, including operating instruments, being only 12 ft long. By contrast the control room in the earlier Queenston development designed in 1920, also a ten-unit plant, is 70 × 74 ft, the main control boards totaling 51 ft in length.

Control-room lighting has been the subject of extensive investigation in recent years, in fact generally higher levels of illumination are found throughout the more modern plants. Air-conditioned and soundproofed control rooms, virtually isolated from the generator floor, are becoming common practice, some form of control pedestal usually being provided adjacent to the unit, an operator on the generator floor performing the simpler operations of starting and shutting down the unit.

With the continued growth of transmission systems, the tendency toward higher voltage and consequently more heavily loaded lines, interconnections between generating plants and the generally higher grade of service the consumer has been educated to expect, the problems of load control, frequency regulation, and the removal of disturbances by means of automatic relays have become more exacting.

Automatic frequency regulation and the corresponding automatic regulation of tie-line loading is gradually finding a place in Canadian practice, though more extensively applied in other countries.

Extremely rapid clearance of line and station disturbances, while retaining proper selectivity, is the object of modern relay applications. It is expected that practically complete solution of stability problems in high-voltage long-distance 25-cycle transmission will be effected by the combination of these relays with the high-speed breakers previously discussed.

Relays for this service usually operate on the impedance or reactance principle, the mechanical designs having been improved to the point where one-cycle operation has been obtained. The application of pilot-type relaying, where the action of the distant end relays may be controlled by impulses of carrier frequency transmitted over the power circuits, is growing to meet the needs of more complicated system connections. Pilot-type control appears to offer a satisfactory solution to such problems as branched or tapped lines, for which no other high-speed types have been found to be entirely suitable.

In general, the necessary potentials for the operation of these relay types are obtained from two-winding transformers. The potentiometer type of potential source, utilizing capacitance principles, is, however, finding increasing service in a number of ways, for example, in resynchronizing high-voltage lines at main receiving stations following an automatic trip-out.

In summary, the electrical side of hydroelectric development is growing in complexity as the demand for power increases. As the number of generating stations operating in parallel increases, either normally or under stress of emergency conditions, so the associated transmission systems become more complicated. To counteract this tendency, the development itself is being designed to effect the maximum possible simplicity.

Designs incorporate in general the minimum number of units (single-unit plants are not uncommon), the simplest electrical connections, with the control removed from human hands in so far as possible by the application of automatic devices. As these trends of themselves tend to promote economical development of available sites, it is to be expected they will continue.

Conclusion

Interconnection of plants and their separate transmission systems, resulting in the building up of large distribution networks in the more populous parts of the country, had a profound influence upon the design and operation of hydroelectric development ten to twenty years ago. Some of the problems of speed regulation and of pressure regulation in long conduits were partially solved by this tendency, more efficient use of limited water supplies was effected, and development of certain sites made economically advantageous. The design of plants to meet the requirements of industry in remote parts of the country has brought about a return of many of the earlier problems of design. Many of the plants so built are quite isolated from all others and must therefore be designed for continuous and reliable service, frequently under very adverse conditions.

Reference has been made already to one plant in northern Ontario, where continuous service has been given for six years with no opportunity for interruptions for maintenance. Moreover, load variations were such as to make much more severe demands on the governing system than would be the case in plants giving ordinary central-station service.

Extensions of transmission systems into many mining districts are taking place, the same tendency toward interconnection of isolated plants and systems being observed as took place in industrial districts some years ago. Large areas in northern Ontario and Quebec, which are dependent mainly on mining activity, are now covered by an extensive network of transmission lines.

Supercharging of Internal-Combustion Engines With Blowers Driven by Exhaust-Gas Turbines

By ALFRED J. BÜCHI,[1] WINTERTHUR, SWITZERLAND

The author discusses the operation of the Büchi exhaust-gas turboblowers for supercharging internal-combustion engines and scavenging the cylinders, and also explains the principles on which the blowers are designed. He presents indicator, temperature, and entropy diagrams for Diesel engines equipped with the blowers, and gives results of tests conducted on the blowers. A number of internal-combustion engines with exhaust-gas turbo-blowers as used in different types of service are described in the paper. The author also presents a number of curves showing the scavenging effect of the blowers, and the brake mean effective pressure, brake horsepower, and fuel consumption obtained on engines using the Büchi system of turbo-charging.

THE THEORY that supercharging blowers for internal-combustion engines can be driven by turbines utilizing the exhaust gases from the internal-combustion engines themselves is in itself not sufficient to give the advanced results now obtained with this method of supercharging. The advantages which at first appeared to be so obvious were not easy to realize. The exhaust-gas turbo-charging of internal combustion engines had to pass through various phases of development for many years before the theory could be adopted in practice and good results could be obtained.

The oldest patents granted in this field date back to the beginning of the present century. Detailed descriptions concerning its adaptation to all kinds of internal-combustion engines were not available before 1909.[2]

The first tests with exhaust-gas turbines in combination with internal-combustion engines were made in 1911 in the Sulzer Works at Winterthur, Switzerland. The experimental plant worked according to the proposals then made by the author. It is worth noting that during these tests supercharging was effected with low pressures and also with pressures up to about 30 lb per sq in. Combustion pressures exceeded 1400 lb per sq in. with over 200 lb per sq in. brake mep.[3]

Influenced by steam-turbine practice, an endeavor was made at these tests to keep the exhaust-gas pressure ahead of the turbine as constant as possible. Piping from the internal-combustion engine to turbine was designed with a comparatively great volume, i.e., as a receiver. When discussing the latest developments of exhaust-gas turbo-charging, we shall see that its success must be ascribed to a great extent to the abandonment of this constant-pressure theory.

When earlier results are compared with the results obtained today, it can be seen that the exhaust temperatures were then much higher for a given load on the internal-combustion engine and therefore the exhaust valves had to be cooled. At that time it was known that fuel consumption could be improved with exhaust turbodrive, in spite of decreased expansion in the combustion cylinder owing to the exhaust back pressure, since mechanical losses due to friction remain practically constant for cylinders of given dimensions even though mean effective pressures are greatly increased.

In Fig. 1 are given indicator, temperature, and entropy diagrams of the 1911 experimental plant for supercharging pressures of 0, 7.1, 14.2, 21.3, and 28.4 lb per sq in. Line *d-e* of the weak-spring diagram in Fig. 2 shows that the exhaust pressure was practically constant during escape into the turbine.

With the exhaust-gas turbine which was used, no difficulties arose in running, and the increased mean effective pressure was taken by the running gear of the engine quite easily without any excessive wear. In order to obtain still further improvements in the results, it was found necessary to introduce the greatest possible weight of charging air into the engine cylinder, in order, for a given swept volume, to obtain a high specific output with low gas temperatures, little transmission of heat, and also high mechanical efficiency.

The present Büchi supercharging system takes full consideration of these requirements. In this system the cylinder is not only charged with precompressed air, but is also scavenged with a great quantity of cool combustion air in spite of placing the exhaust-gas turbine after the internal-combustion engine and the consequent back pressure in the exhaust.

It was not so easy to find a suitable working process. Because of the rather low efficiencies of the exhaust-gas turbine and the centrifugal blower driven by it for a certain supercharging pressure, approximately the same exhaust-gas pressure as the blower pressure is necessary to drive the turbine with the given temperatures of the exhaust gases. Consequently, a pronounced pressure

[1] Consulting Engineer. Mr. Büchi was graduated from the Swiss Federal Institute of Technology, Zurich, Switzerland, in 1903 with an M.E. degree. Prior to these studies he passed a three years' practical training in the shops of Sulzer Brothers, Winterthur, Switzerland. From 1903 to 1906 he served as designer of Diesel engines, gas engines, and steam engines at the S.A. des Ateliers Carel Frères, Ghent, Belgium. He made a study tour in England in 1907. During 1908 he was engaged as consultant with Honegger Company, Wetzikon, Switzerland, builders of mechanical equipment. From 1909 to 1918 he was chief of the research department for Diesel engines in the Sulzer Brothers' plant at Winterthur. He served as chief engineer in charge of marine Diesel engines, Howaldtswerke, Kiel, Germany, from 1918 to 1919 and from 1919 to 1927 as chief engineer in the Diesel Engine Department of Sulzer Bros., Winterthur. In 1927 he began the organization of the Büchi syndicate for the development of his supercharging system. From 1928 to 1934 he was managing director of the Swiss Locomotive and Machine Works, Winterthur. Since then he has served as head of the Büchi Syndicate, Winterthur.

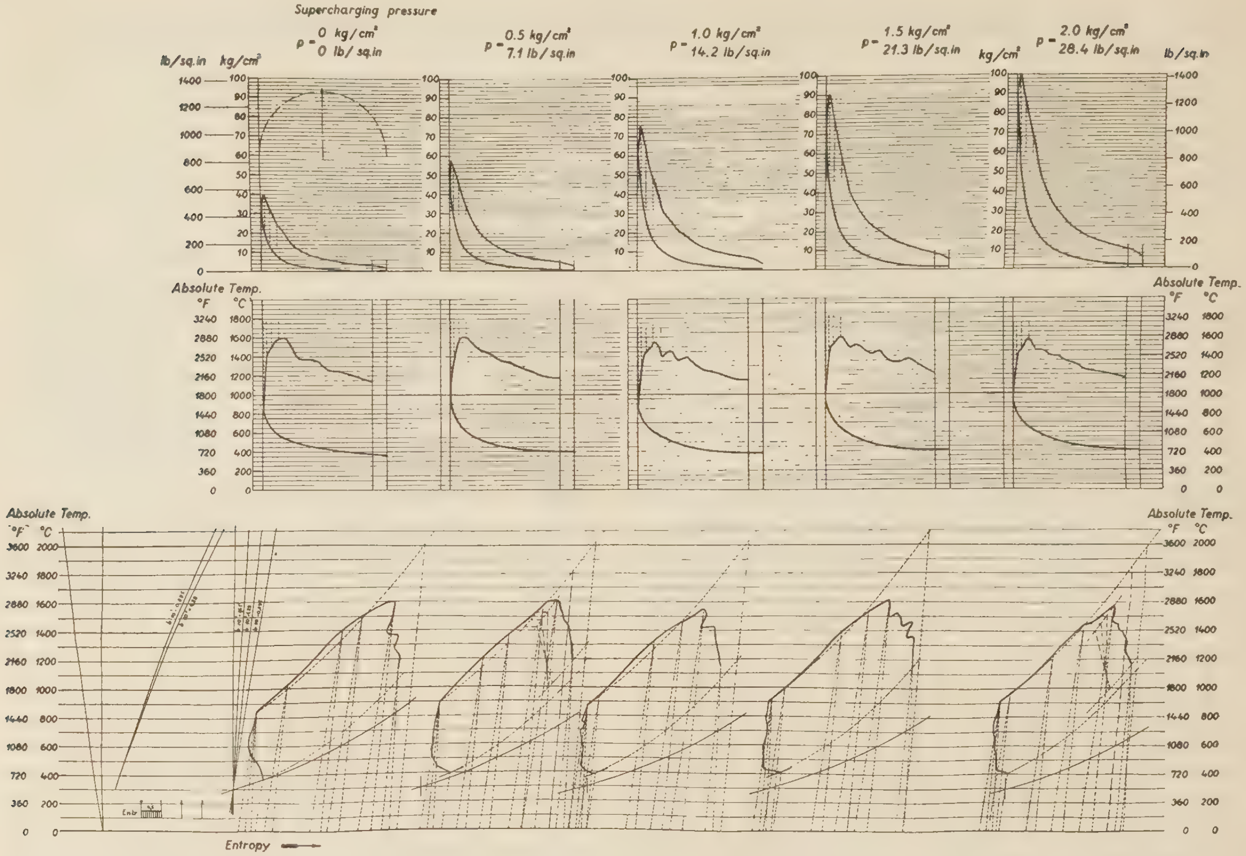

FIG. 1 INDICATOR, TEMPERATURE, AND ENTROPY DIAGRAMS OF THE FIRST DIESEL ENGINE EQUIPPED WITH AN EXHAUST-GAS TURBOBLOWER FOR SUPERCHARGING AND SCAVENGING

difference between charging air and exhaust gases, which is required for an effective scavenging of the working cylinders, is not available. To overcome this pressure condition, the Büchi system makes use of a device which controls to any desired degree the pressure drop required between the supercharging pressure and the exhaust-gas pressure ahead of the turbine. This is effected by means of strong pressure fluctuations artificially caused in the piping between engine and exhaust-gas turbine.[4,5] These fluctuations are created between engine and turbine by choosing suitable cross sections for the exhaust-gas turbine and the volume and cross section of the exhaust piping. Their occurrence at the correct moment and their correct repetition in each working cycle are insured by suitable adjustment of the exhaust valve gear of the engine. Care must also be taken that these forced oscillations are always similar and occur at the proper moment for any given engine load, regardless of different speeds of rotation; also that they are not distorted or even possibly stopped by other effects, such as oscillations in the exhaust pipes. This can be prevented by using proper control gear for the exhaust valves and by choosing suitable dimensions for the exhaust pipes leading to the turbine.

If the working cylinders have to be scavenged, the inlet and outlet means must be open simultaneously during the scavenging period. Also, the scavenging process must not under any consideration be disturbed by the exhaust occurring from another cylinder. If there is disturbance, the gases from the exhausting

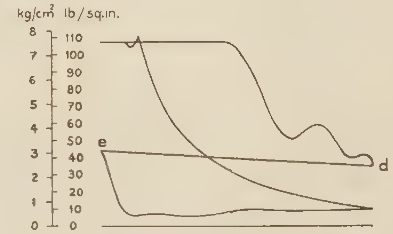

FIG. 2 WEAK-SPRING INDICATOR CARDS TAKEN ON THE FIRST DIESEL ENGINE EQUIPPED WITH AN EXHAUST-GAS TURBOBLOWER

cylinder will find their way through the open exhaust valves into the cylinder that has to be scavenged. This trouble occurs when all cylinders of an engine exhaust into the same exhaust manifold. It is eliminated in the Büchi system by leading the exhaust gases from the engine to one or more turbines through several exhaust pipes, or through exhaust pipes fitted with suitable partitions. In the Büchi system, pipes are arranged so that the exhaust process in one cylinder cannot interfere with the scavenging process in another cylinder. The separation of the exhaust pipes is carried down to the admission nozzles at the turbine, so that it is also impossible for the gases to flow back through the turbine.

The number of cylinders exhausting into one pipe, the time in each cylinder when exhaust begins and stops, and also when admission begins, must be chosen in such a way that no mutually harmful effects may occur. This adjustment must be chosen in various ways to suit the circumstances and in accordance with the number of cylinders.

[5] "Pressure Fluctuations in Exhaust Piping," by E. H. Abt, *The Motorship*, London, vol. 12, June, 1931, p. 102.

In Fig. 3 are given the pressure oscillations for various loads in one of the two exhaust pipes of a six-cylinder Diesel engine with exhaust turbo-charging. These were taken by electric indicators and oscillographs. The ignition interval within a group of cylinders amounted to a crank angle of 240 deg. The opening of the exhaust and inlet valves, in terms of crank-angle degrees, is indicated at the bottom of Fig. 3. The period between the initial opening of the inlet valve and the closing of the exhaust valve is designated as the scavenging period. Referring to the pressure variations shown in Fig. 3, it will be seen that at all loads a pronounced depression of the exhaust-gas pressure occurs before the turbine and continues during the whole scavenging period; this is shown by the shaded areas between the approximately constant charging air-pressure curves and the extremely variable exhaust-pressure curves. With 79.5 lb per sq in. brake mep, the exhaust pressure falls to about atmospheric. With higher mean effective pressures it is almost as low, but the pressure peaks of the exhaust pressure and the charging-air pressure are in these cases much higher; this is caused by the

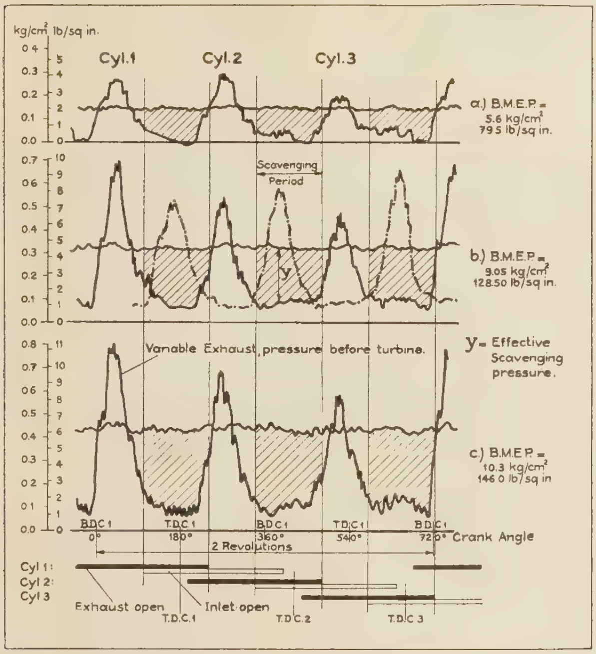

Fig. 3 Pressure Oscillations for Various Loads in Two Exhaust Pipes of a Six-Cylinder Diesel Engine With Exhaust-Gas Turbo-Charging

increase in the quantity of exhaust gas and in its temperature with increasing loads.

The pressure oscillations of the other three cylinders of the same six-cylinder engine, which exhausted into a separate exhaust pipe to the turbine, are to be considered as displaced by 120 deg; this is indicated by dotted lines in the middle diagram of Fig. 3. It can be seen clearly that it would be impossible to scavenge the working cylinders if the exhaust pipes were not separated. Fig. 3 also shows the effectiveness of the method of scavenging discussed here.

How the quantity of scavenging air adjusts itself to the load on the engine can be seen from Fig. 4. Curve a corresponds to an engine in which the load was altered at constant speed, that is, a stationary-type engine. Curve b on the other hand corresponds to a marine engine, in which the load was decreased by reducing the speed in accordance with the propeller law. Curve a was obtained from an SLM Diesel engine with eight cylinders, developing 1000 bhp at 273 rpm with continuous supercharging, while curve b is from an eight-cylinder Harland & Wolff (Kincaid) marine Diesel engine developing continuously 4500 bhp with supercharging. The speed of the latter engine is 112 rpm. The speeds of the corresponding blowers are also plotted in Fig. 4 as curves c and d, respectively.

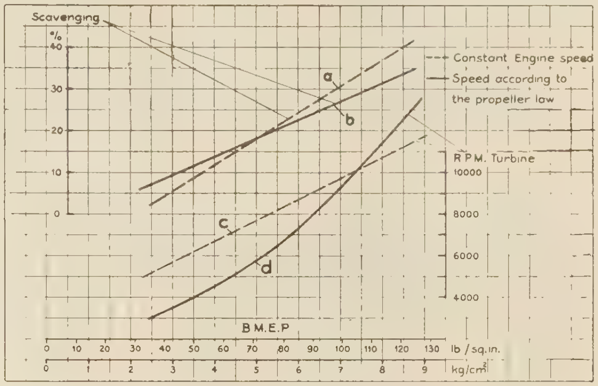

Fig. 4 Scavenging Percentages and Speeds of Exhaust-Driven Turboblowers on Four-Cycle Stationary and Marine Diesel Engines

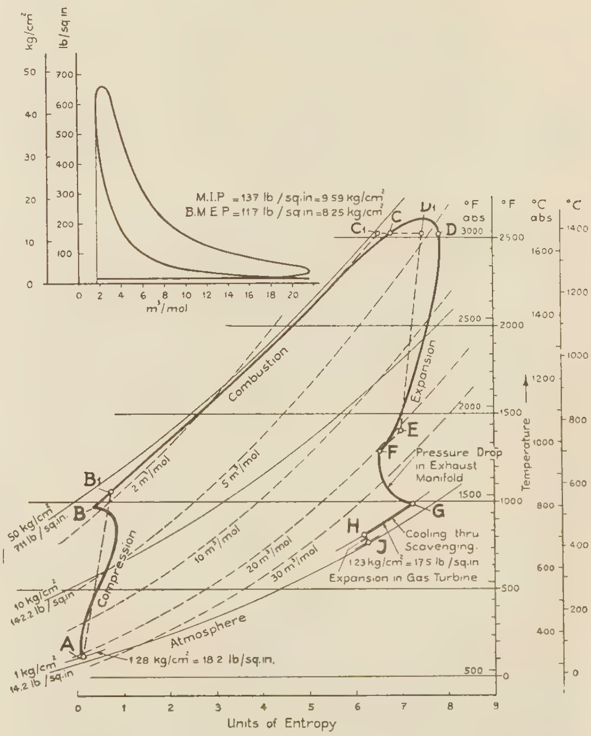

Fig. 5 Entropy and Indicator Diagrams of a Diesel Engine With Exhaust-Gas Turbo-Charging

In Fig. 5 the conditions of pressure, volume, and temperature of the working process with the Büchi exhaust turbo-charging are shown by an entropy diagram. The values plotted were obtained from tests on a Franco Tosi six-cylinder Diesel engine with exhaust turbo-charging. The compression is shown as AB, while BCD represents the combustion, and DF represents

the expansion in the working cylinder. At F the exhaust valves open, and the exhaust gases flow to the turbine, at the same time expanding as indicated by FG. The cooling of the exhaust gases on their way from the cylinders to the exhaust turbine, and particularly their cooling by means of scavenging air passing through the cylinders is shown as GH. Before the exhaust valve begins to open, according to the point F, the gases have a temperature of 967 C abs, or 694 C (1282 F). Due to the pressure drop ahead of the turbine, corresponding to FG, the temperature falls to 532 C (989 F). With 27.4 per cent excess scavenging air, the exhaust gases from the condition at G to their condition at H are cooled to 435 C (815 F). The cooling resulting from scavenging is therefore 97 C (174 F), including a loss of heat of approximately 5 C (9 F). During the expansion of the gas in the turbine, the temperature drops from H to J, or to 407 C (765 F). Therefore, this latter drop amounts to only 28 C (50 F).

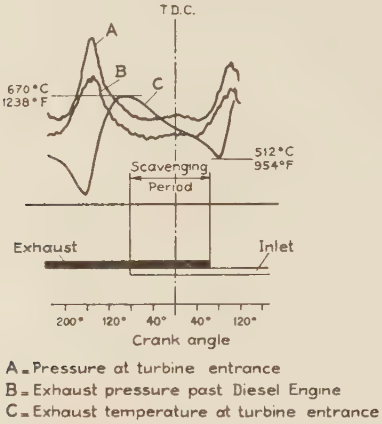

FIG. 6 TEMPERATURE AND PRESSURE VARIATIONS DURING THE EXHAUST AND SCAVENGING PERIOD IN THE EXHAUST MANIFOLD BETWEEN THE ENGINE AND EXHAUST-GAS TURBINE OF A MAN DIESEL ENGINE

The diagram A, B_1, C_1, D_1, E, F, shown in dashed lines, is a theoretical diagram drawn from calculated values having 17.7 per cent heat loss during combustion and expansion, and 4 per cent loss at the beginning of the exhaust; the actual diagram is shown as the solid line A, B, C, D, E, F. Transferring the points of the diagram to pressure-volume coordinates gives the indicator diagram shown in Fig. 5 above the entropy diagram. From this the corresponding indicated pressure can be determined. The mechanical efficiency of the engine in question was measured and found to be 86 per cent. The effective output and the fuel consumption can be calculated from the indicator diagram. Based on the indicator diagram in Fig. 5, the effective output of a six-cylinder engine, of 450 mm (17.7 in.) bore and 700 mm (27.55 in.) stroke, is found to be 1060 bhp[6] at 187 rpm, with 109 lb per sq in. brake mep. The fuel consumption is found to be 160 grams, or 0.353 lb per bhp-hr.

In the entropy diagrams, HJ represents the expansion in the exhaust-gas turbine. Its effective output must be equal to the power required for driving the air charging blower. The symbols used in the calculations are:

G_1 = weight of air delivered for charging and scavenging
R = gas constant for air
T_1 = absolute temperature for the air at blower inlet
p_1 = absolute initial pressure of the air delivered
p_2 = absolute final pressure of the air delivered

[6] In all references to horsepower, metric horsepower is intended.

η_K = isothermal efficiency of the charging and scavenging air compressor
$L_{e(K)}$ = effective work done in compressing the charging and scavenging air, or

$$L_{e(K)} = \frac{1}{\eta_K} \times G_1 \times R \times T_1 \log_e \left(\frac{p_1}{p_2}\right)$$

G_2 = weight of exhaust gases passing through the turbine
c_p = specific heat of the exhaust gases at constant pressure
A = mechanical heat equivalent
t_1' = absolute temperature of exhaust gases ahead of the turbine
t_2' = absolute temperature of exhaust gases after adiabatic expansion in the turbine
G_2 = G_1 + quantity of fuel introduced = kG_1
η_T = adiabatic efficiency of the exhaust-gas turbine
$L_{e(T)}$ = effective output of the exhaust-gas turbine, or

$$L_{e(T)} = \eta_T \times G_2 \times \frac{c_p}{A}(t_1' - t_2') = L_{e(K)}$$

Therefore, the effective temperature drop required in the exhaust-gas turbine is

$$t_2' - t_1' = \frac{1}{k\eta_K\eta_T}\,\frac{RT_1}{c_p \times 428} \log_e \left(\frac{p_1}{p_2}\right)$$

From the foregoing, the action of the supercharging system can be clearly seen. The entire working process takes place at all load factors because the charging air is compressed and on account of the inner cooling of the engine through scavenging air with a low specific volume. In this way, with the same excess air as in ordinary internal-combustion engines without supercharging and scavenging, the indicated pressure becomes much greater. Therefore, for a given output, a smaller cylinder volume is satisfactory. This again results in lower thermal and frictional losses. Increasing the output of the engine per unit of volume therefore implies less thermal losses through cooling and a considerable improvement in the mechanical efficiency, and consequently an improvement in starting conditions. The manifold effects of the scavenging air are of the utmost importance. These effects are:

1 Freeing the compression space from traces of the hot exhaust gases, in contrast to ordinary internal-combustion engines without supercharging. Cooling the cylinder walls and the valves lowers the initial temperature of the working process and thereby increases considerably the weight of combustion air enclosed in the cylinder.

2 Not only the swept space, but also the compression space, is filled with fresh air suitable for combustion. This makes itself apparent in service in perfect combustion and a great capacity for taking overload.

3 The quantity of heat passing away through the cooling water is less, since a part of the heat given up to the cylinder walls is absorbed direct by the cold scavenging air. However, this heat is not lost, but usefully employed in the turbine. This also explains the high thermal efficiency.

4 Mixing the exhaust gases with the cool scavenging air allows the exhaust-gas turbine to run under favorable conditions; complicated cooling devices for the turbine wheels are rendered unnecessary. Consequently, the loss of heat caused by such cooling is absolutely eliminated.

Fig. 6 illustrates the effect of the scavenging. It shows the temperature and pressure course during the exhaust and scavenging period measured in the exhaust manifold ahead of the turbine of a Diesel engine. Curve A represents the exhaust pressure at the turbine entrance and curve B represents the exhaust pressure just past the exhaust valve. This latter pressure is lower on

account of the high velocity and kinetic energy of the gases. Curve *C* represents the temperature changes. The very pronounced drop of the temperature during the scavenging period can clearly be recognized.

A number of internal-combustion engines for different types of service using exhaust-gas turbo-charging are described in the remaining part of the paper, and the results obtained with them are mentioned.

Stationary and Marine Diesel Engines

Fig. 7 shows results obtained in a stationary Diesel-engine plant equipped with two, six-cylinder, MAN, four-cycle engines with exhaust-gas turbo-charging. The exhaust turboblowers are arranged in a compartment next to the engine room, at such a height that the two exhaust pipes from the engines run horizontally to the exhaust-gas turbines. The plant works with a waste-heat recuperator which is fitted after the turbine. In the most favorable case, the fuel consumption is less than 0.36 lb

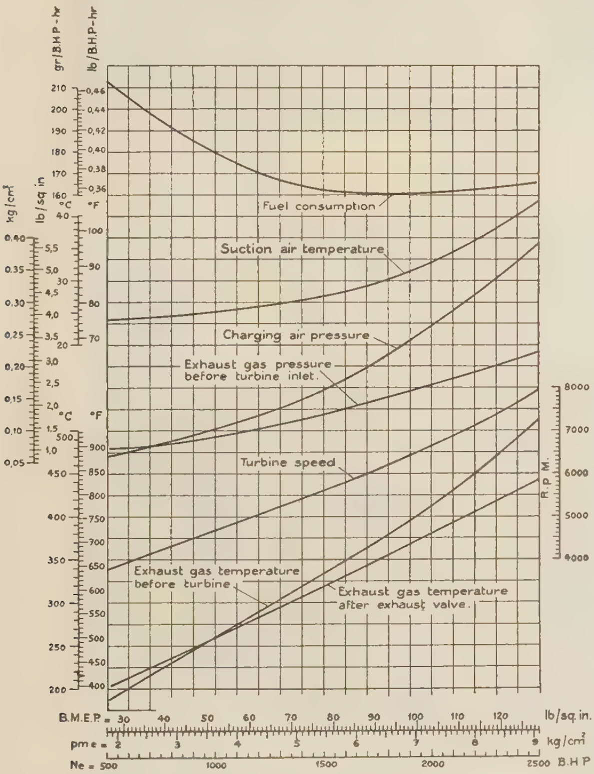

Fig. 7 Test Results of a Six-Cylinder 2250-Bhp MAN Diesel Engine Equipped With Exhaust-Gas Turbo-Charging

per bhp-hr. In spite of the high suction temperature of the air at which the plant is operated (up to 102 F) the exhaust-gas temperatures measured after the valves remain somewhat under 800 F at 120 lb per sq in. brake mep.

In Fig. 8 the results obtained with an SLM Winterthur Diesel engine are plotted. At full load the fuel consumption is 0.36 lb per bhp-hr and the fuel-consumption curve is extremely flat, as with all Diesel engines with exhaust-gas turbo-charging. This means that the consumption at low load is also very small; at 1/4 load it is from 20 to 25 per cent less than that of an ordinary Diesel engine with the same load factor. The excess scavenging air is also plotted in Fig. 8; at full load it increases to over 30 per cent.

An SLM-Winterthur engine with exhaust turbo-charging is shown in Fig. 9. This engine has three cylinders and develops 450 bhp. In this engine, which is installed in the laboratory of the Federal Technical University in Zurich the turbine is mounted in a vertical position directly on top of the engine.

An arrangement of the exhaust-gas turboblower mounted on the forward end of a Humboldt-Deutz eight-cylinder Diesel engine is shown in Fig. 10. The exhaust gases pass downward

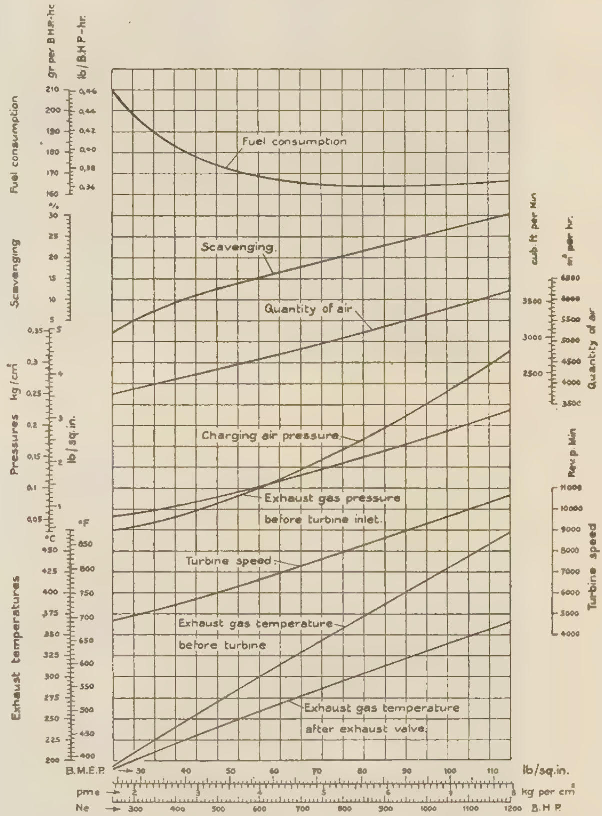

Fig. 8 Test Results of an Eight-Cylinder 1000-1200 Bhp SLM Diesel Engine Equipped With Exhaust-Gas Turbo-Charging

from the turbine through a vertical pipe. Below the turbine and immediately to the right of it, may be seen the flexible expansion joints which have been inserted in order to prevent the turbine from being damaged by the expansion of the exhaust pipes.

In general it can be said that the reduction in the dimensions and weights of the engines which is obtained as a result of the increase in output through exhaust-gas turbo-charging, is of course reflected in price of the engines, and in stationary installations it has also the following advantages: For example, the engine building becomes smaller and the foundations can be of lighter construction. As a result of the reduced cooling required, less cooling water has to be provided, thus leading to further savings, especially when water is scarce, and in cases where it is necessary to erect cooling towers. The reduced fuel consumption also plays an important part, especially when the engine is working with variable loads. In four-cycle engines it is also possible to adopt a rational method of utilizing waste heat in the exhaust gases.

The MS *Reina del Pacifico* of the Pacific Steamship Company

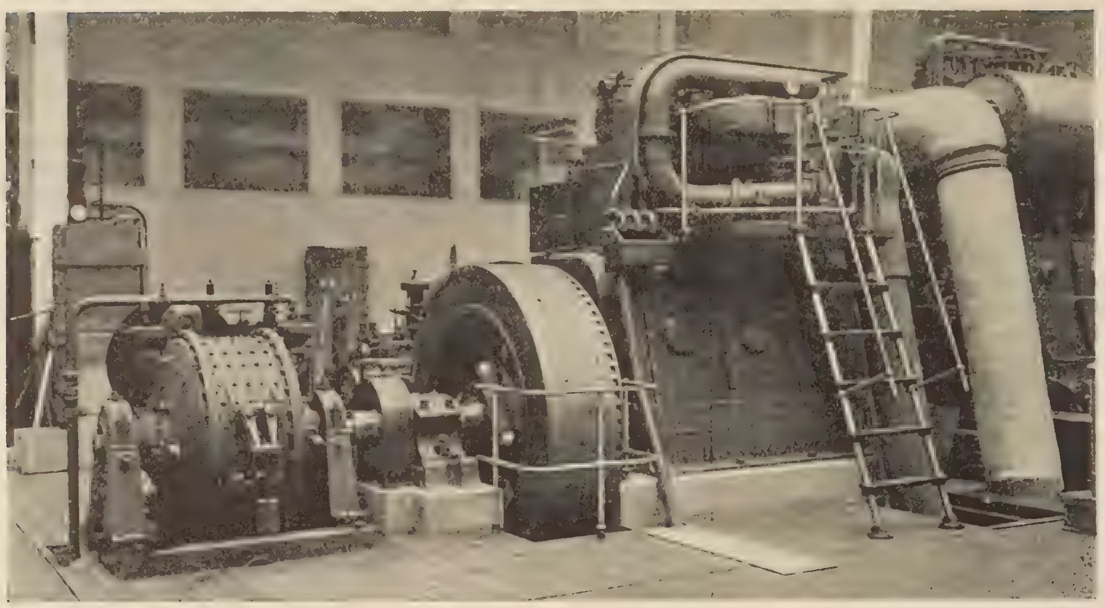

Fig. 9 Three-Cylinder 450-Bhp SLM Diesel Engine With Vertical Exhaust-Gas Turboblower

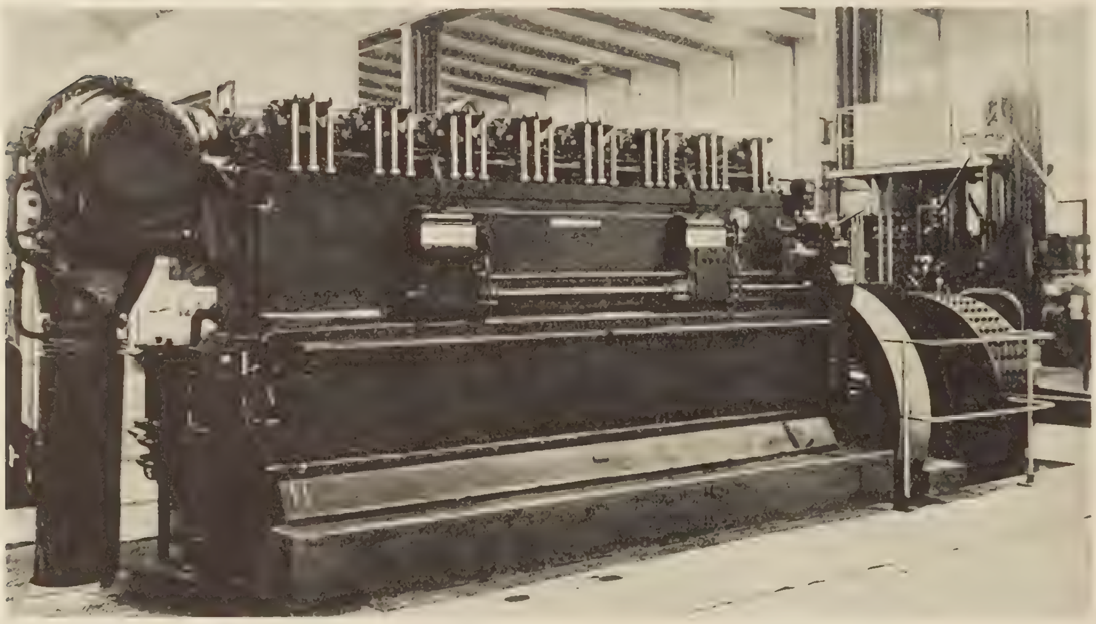

Fig. 10 Eight-Cylinder 750-Bhp Deutz Diesel Engine With Exhaust-Gas Turboblower Mounted Horizontally at the End of the Engine

in service between England and the West Coast of South America via the Panama Canal, is propelled by four, 12-cylinder, Harland & Wolff, single-acting four-stroke trunk-piston engines with exhaust-gas turbo-charging. The trunk-piston design gives an engine very low in height, so that many continuous decks could be arranged far down in the ship. Two cranks in each of the 12-cylinder engines are set the same, and their firing order is also the same. Consequently, in order to avoid trouble in the cylinders during the scavenging period (to which reference has already been made) there are only two exhaust pipes provided for each engine. The exhaust-gas turbines are arranged in an extension of the engine room. After leaving the turbines, the exhaust gases can be led to waste-heat recuperators. Noteworthy in this plant is also the comparatively small size of the auxiliary Diesel-engine plant, a great contrast to Diesel installations with electrically driven charging or scavenging air blowers. As is well known, such installations require large Diesel engines for generating electric energy. With exhaust-gas turbo-charging, the generation of electric energy for the charging air blowers is not required, since the blowers are driven by the exhaust gases from the Diesel engine, without any outside assistance.

Besides for the merchant service, Diesel engines with exhaust

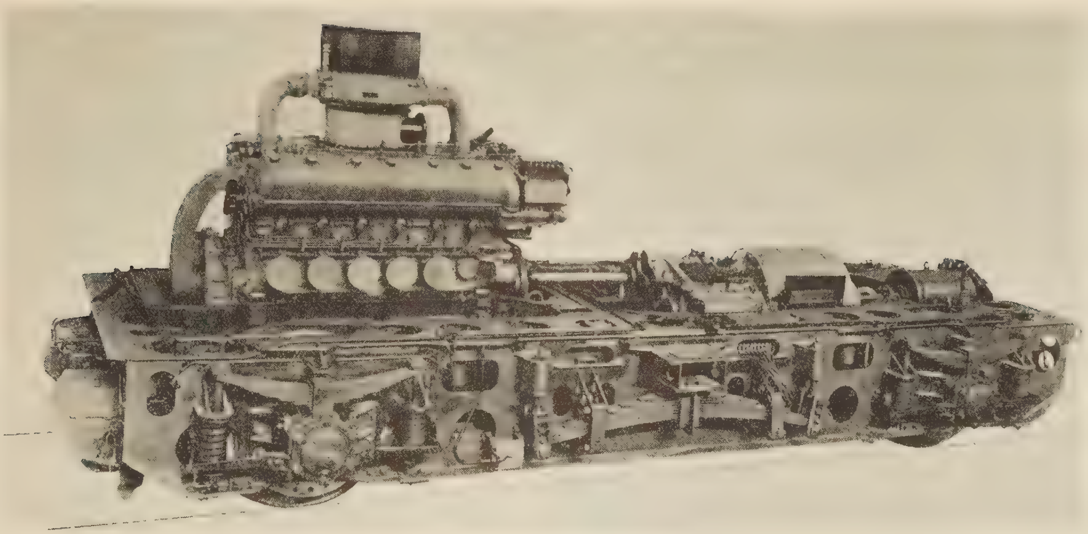

Fig. 11 Rail-Car Truck With a Maybach 12-Cylinder V Diesel Engine. The Engine Has a $6^{5}/_{16}$-In. Bore an 8-In. Stroke, Operates at 1500 Rpm, and Develops 700 Bhp

turbo-charging are particularly interesting for naval vessels. Here, as is well known, small dimensions, low weights and low fuel consumption are of decisive importance, especially at low loads for cruising. On the other hand, the high capacity for overload of the supercharged engines is of great interest for running at full speed.

In ships with Diesel-electric drive, engines with exhaust-gas turbo-charging have already been installed in several cases. One such case is the light cruiser Ilmarinen of the Finnish Navy. Four, high-speed, Krupp Diesel engines, each of 1200 bhp, are installed in this vessel. Because of the high speed of these engines and their being fitted with exhaust-gas turboblowers, it was possible to keep the weight of the machinery comparatively low and to have the engine room small; greater weight could consequently be allowed for the armored plating and the armament.

Each of ten, high-speed, custom-house boats for Mexico were, for reasons of space and weight saving, equipped with two 1350 bhp MAN Diesel engines with exhaust-gas turboblowers.

With regard to the use of exhaust-gas turbo-charging in ships, it may in general be stated that the reduced dimensions and weight of the machinery offer still more pronounced advantages than in stationary plants. The carrying capacity of a vessel is increased, or a vessel may be built of smaller dimensions for the same carrying capacity. The lower fuel consumption increases the radius of action, and marine engines, particularly in the merchant service, have often to run for lengthy periods; a correspondingly greater quantity of cargo can be carried. Because of the smaller dimensions of the cylinders and bearings, the lubricating-oil consumption is also reduced. Engines with smaller cylinder dimensions also require smaller, and consequently cheaper spare parts.

Experience with the many installations now in service has shown, that the reliability of the exhaust-gas turboblowers is excellent.

Traction Diesel Engines

A 1400 bhp Diesel locomotive of the German State Railways is equipped with an eight-cylinder MAN Diesel engine with exhaust-gas turbo-charging. The exhaust-gas turbine and blower are fitted at the flywheel end of the engine, which is located approximately in the middle of the locomotive. No silencer is provided, the exhaust being made direct to atmosphere. The overall length of the locomotive is 47 ft, and the service weight is 75 tons. Its speed is over 60 mph.

Fig. 11 shows a truck of a rail car used on the German State Railways, with a Maybach 12-cylinder V Diesel engine with exhaust-gas turbo-charging. The supercharger is arranged vertically in the middle between the two rows of cylinders. In these engines, of which the German State Railways have a large number in service, a weight of 9 lb per bhp was obtained through the use of exhaust-gas turbo-charging. The engines run at 1500 rpm and can be loaded up to 700 bhp.

Figs. 12, 13, and 14 show the results obtained with a six-cylinder engine of 130 mm (5.12 in.) bore and 170 mm (6.7 in.) stroke operating at a maximum speed 1500 rpm. At 1500 rpm, about the limit of invisible exhaust, 135 lb per sq in. brake mep was reached. As shown in Fig. 14, remarkably low fuel consumption was obtained at speeds varying from 1000 to 1500 rpm.

It can be said that the adoption of exhaust-gas turbo-charging is of pronounced advantage for locomotives and rail cars. An important part is played not only by the reductions made in dimensions, weight, and fuel consumption, but also by the possibility of the adoption of supercharging to get an engine of the required output mounted in such a traction unit.

In traction service, the size of the water and oil-cooling devices is also of importance, first, because of their weight and the space requirements, and second, because of the power required for driving their fans. In this connection the Diesel engine with exhaust-gas turbo-charging proves to be the most advantageous, since in the most unfavorable case it requires coolers and fans about 30 per cent smaller for the same output.

As a result of the small losses through friction in the smaller pistons and bearings, as previously mentioned, the torque required for starting such an engine against no load is also less. Consequently, starting devices of smaller capacity can be used for starting.

Another important point is the fact that, because of the less heat led away, up to 50 per cent more output can be developed with engines without piston cooling. This is of particular significance in engines for traction, but it often plays an important

part in marine and stationary engines. As is well known, piston-cooling devices always give rise to difficulties sooner or later, so that their elimination is of much importance and is, in fact, stipulated in many cases.

Engines with precombustion-chamber fuel injection have been equipped in several instances with exhaust-gas turbo-charging. For example, a Daimler-Benz, six-cylinder engine which develops 180 bhp at 1500 rpm has been so equipped.

Airplane Engines

The use of exhaust-gas turboblowers with airplane engines has already been made in various cases, first of all with gasoline engines. But in engines working with carburetors, no scavenging of the working cylinders is possible; the increased output attained is therefore small, and the temperatures before the turbine become so high as to cause many difficulties. The Büchi exhaust-gas turbo-charging in combination with mechanical gasoline injection, whether into the suction manifold of the engine, or into the working cylinders themselves, allows these engines to be scavenged efficiently. It is merely necessary to take care that the gasoline injection begins after the scavenging, with precompressed fresh air, has been completed. If this is the case, the Büchi system of exhaust-gas turbo-charging can be adapted to gasoline-driven airplane engines and will give the same advantages as in Diesel engines. It can of course be used with Diesel airplane engines without any special considerations.

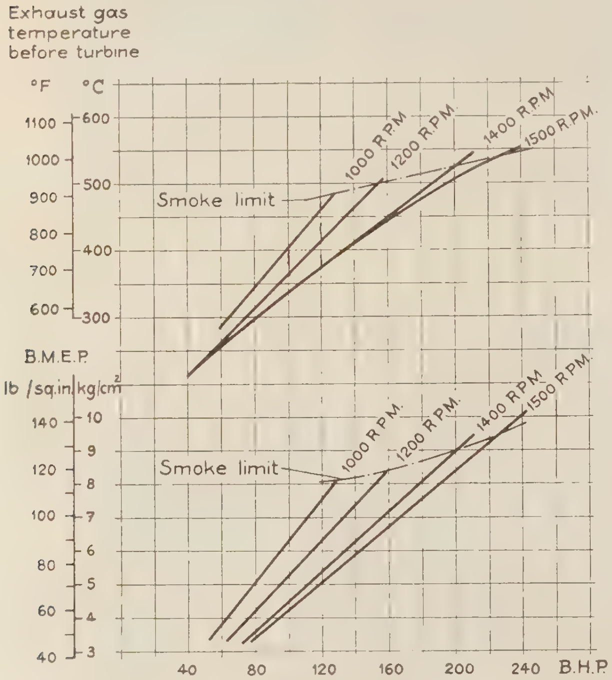

Fig. 12 Exhaust Temperatures and Brake Mean Effective Pressures at Various Loads and Speeds Observed During the Tests of 225-Bhp Six-Cylinder Saurer Diesel Engine Equipped With Exhaust-Gas Turboblower

For obvious reasons, it is not possible at present to give any particulars concerning the adoption of the Büchi system of exhaust-gas turbo-charging to airplane engines. It is, however, a most effective means of compensating, up to the greatest altitudes, for the loss of output caused by the rarefied air. It can also be used to increase the output near the ground level considerably, so that the climbing speed of the airplane becomes greater. The reduced fuel consumption obtained by adopting this system is also of great importance when flying long distances.

Two-Cycle Internal-Combustion Engines

The Büchi exhaust turbo-charging can be used also with two-cycle Diesel engines. Tests in connection with this type of engine have already been made and will be continued. Because of the lower temperatures of the exhaust gases, the results obtained by adopting this system depend greatly on the size and design of the engine in question. However, by adopting special methods of carrying out the charging and scavenging processes, an appreciable increase in output can be obtained.

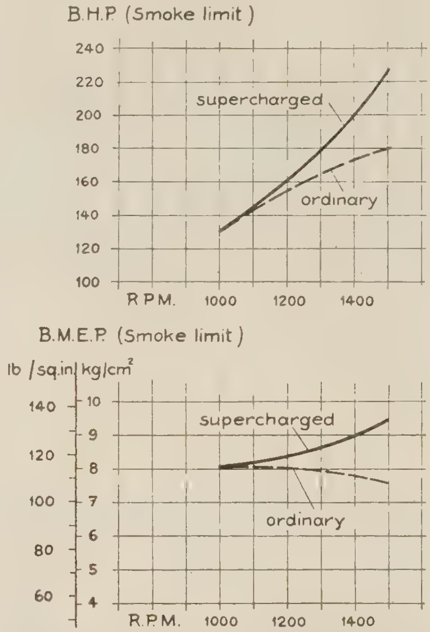

Fig. 13 Variations of Brake Horsepower and Brake Mean Effective Pressures at Various Speeds of a 225-Bhp Six-Cylinder Saurer Turbo-Charged Diesel Engine

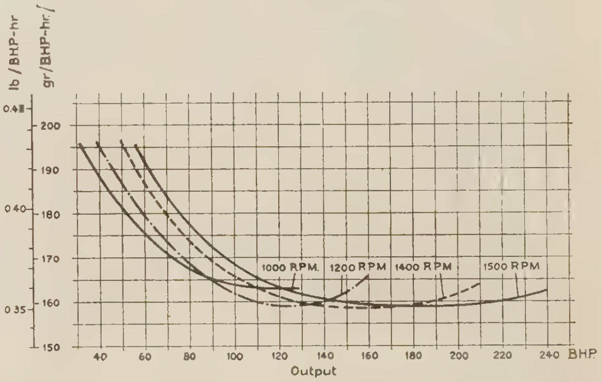

Fig. 14 Fuel Consumption at Different Speeds of a 225-Bhp Turbo-Charged Diesel Engine

Gas Engines

In addition to the engines previously described which work with liquid fuel, gas engines may also be supercharged by blowers driven by the exhaust gases and some installations have already been made. In order that the cylinder may be scavenged, it is

necessary (just as with engines working with gasoline), that the fuel, i.e., the gas, should be admitted only after the scavenging period has terminated.

Air Charging Blowers Driven by Exhaust-Gas Turbines

A section through a vertical blower built by Brown, Boveri & Company, is shown in Fig. 15. This is a single-stage blower, driven by a single-stage turbine, and is the type usually adopted today. Two-stage blowers are used for higher supercharging, especially to compensate for higher altitudes. The runner is

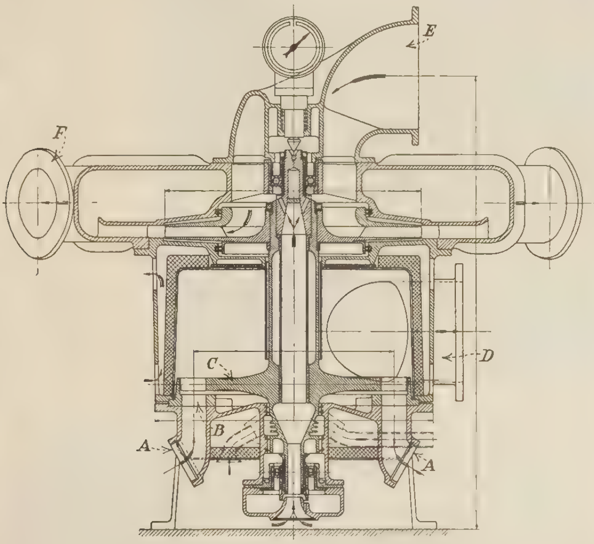

Fig. 15 Section Through Brown, Boveri Vertical Exhaust-Gas Turboblower

runner, with the turbine wheel to the left and the blower impeller to the right. Below, to the left can be seen the admission nozzle ring for the turbine, and to the right the diffuser for the blower.

These blower sets are small in comparison with the internal-

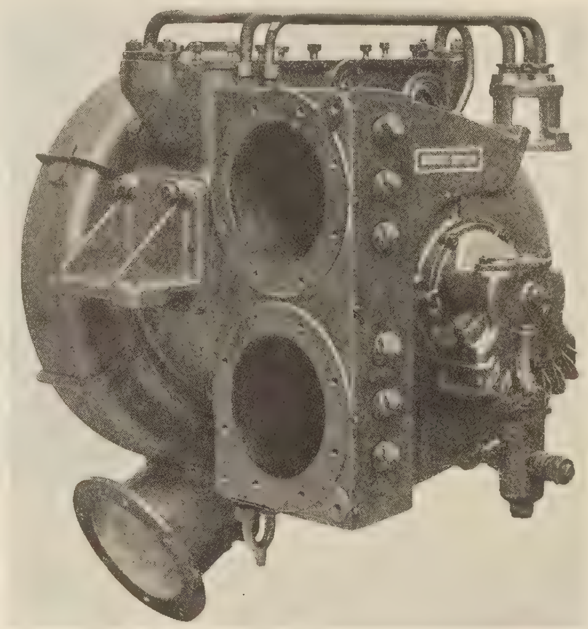

Fig. 16 Turbine End of a Horizontal Brown, Boveri Exhaust-Gas Turboblower With Water-Cooled Turbine Casing

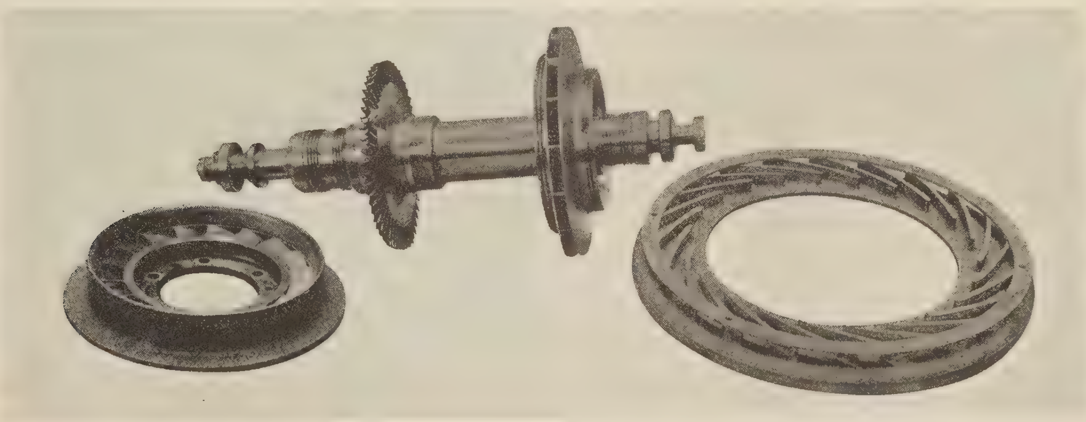

Fig. 17 Runner, Turbine-Nozzle Ring, and Blower Diffuser of a Brown, Boveri Exhaust-Gas Turboblower

carried outside in ball bearings. The exhaust gases enter at A and pass through the nozzle ring B to the turbine blading of the runner C. At D the exhaust gases leave the turbine. The charging air enters at E and leaves at F.

A view of a horizontal blower, seen from the turbine end, is given in Fig. 16. It can be seen that the turbine has two separate inlets for the exhaust gases. The sealing air is led through a pipe from the delivery branch of the blower to the stuffing box of the exhaust-gas turbine. An air filter is fitted at the inlet end of the blower. In Fig. 17 the three most important parts of such a set can be seen in detail. Above, in the center, is the

combustion engines and they can, as already mentioned, be very conveniently mounted, since they generally require no particular room, but can be located in any available free space. Their weight is also low, particularly in the type used for high-speed engines for airplane and traction purposes. For a 500- to 1000-hp airplane engine it is possible to build an exhaust-gas turboblower weighing approximately 100 to 150 lb. Naturally, light metals must be extensively employed.

Many exhaust-gas turboblowers have been built for engines developing up to 6000 bhp. Such a blower is shown in Fig. 18. This was built by Harland & Wolff, Belfast, and has four separate

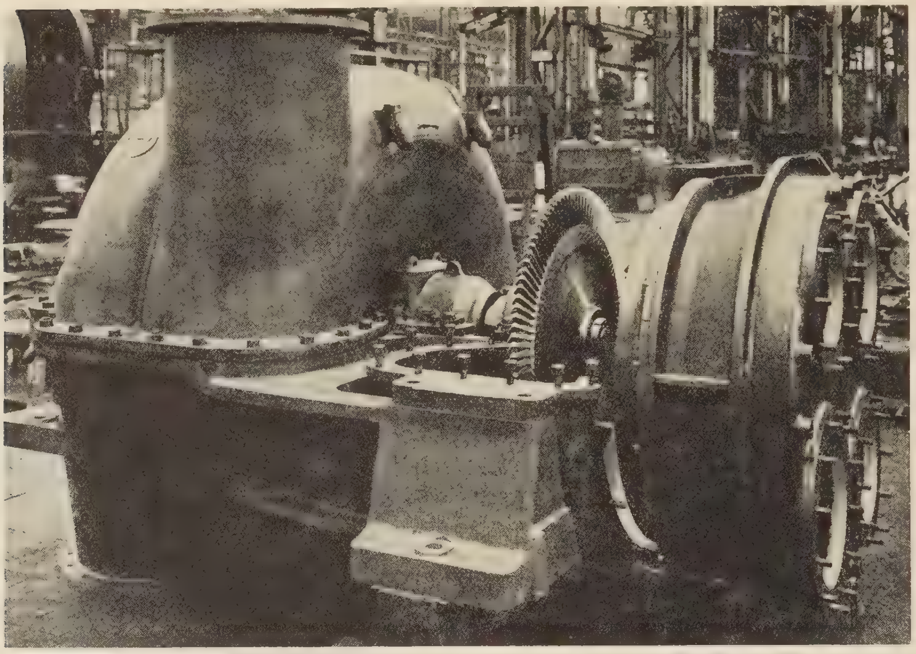

Fig. 18 Exhaust-Gas Turboblower for 6000-Bhp Diesel Engines

gas inlets to the turbine, since it works in connection with a ten-cylinder Diesel engine. On the other hand, however, exhaust-gas turbo-charging has also been adopted for very small engines; it will be interesting to note that Brown, Boveri & Company have already built blowers for 80-hp engines giving them a supercharged continuous output of 120 bhp.

Some Particular Features of the Büchi Exhaust Turbo-Charging System

Behavior When Starting and When Suddenly Loading the Engine. In Fig. 19, the speed of the engine and blower, and also the output of the engine, are plotted as functions of the starting time. The results were obtained with a 1000-bhp Diesel engine, started in the cold state at no load and run idle up to normal speed. A 12-sec period was required for this starting. The engine was then put on load at once by suddenly cutting in the generator which it was driving. It can be seen that the normal output of 1000 bhp was reached in 13 sec from idling. When starting, the speed of the charging blower was brought up to 4800 rpm at no load. The time required to attain its normal speed of 10,200 rpm at full output of the engine was somewhat more than 13 sec. Nevertheless, it can be seen from Fig. 19 that the charging blower is accelerated very quickly—in fact, almost instantaneously—when load is thrown on the engine. The reason for this is that the rotors of the turbine and blower are extremely light and frictional resistance is very low, due to their being carried in two roller bearings.

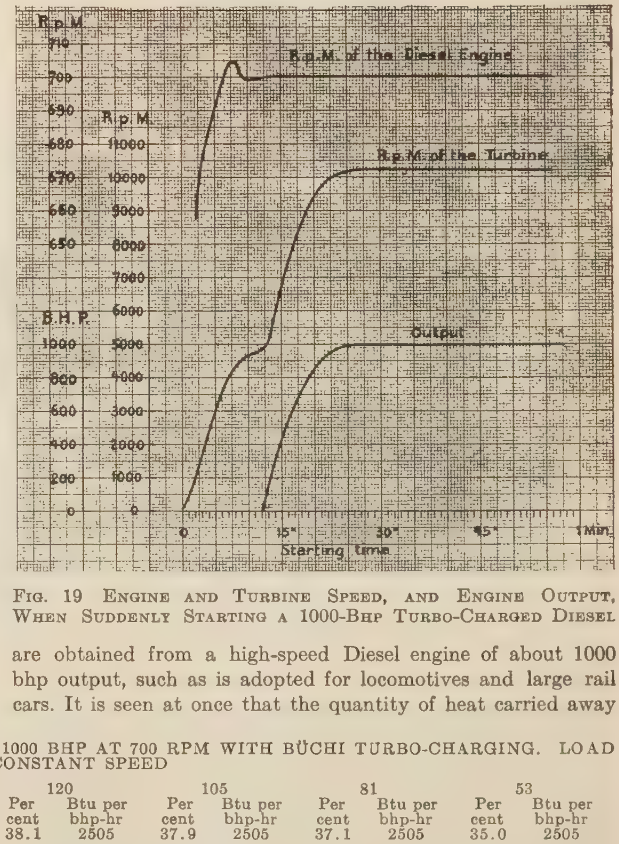

Fig. 19 Engine and Turbine Speed, and Engine Output, When Suddenly Starting a 1000-Bhp Turbo-Charged Diesel

Heat Balance. A heat balance is given in Table 1. The figures are obtained from a high-speed Diesel engine of about 1000 bhp output, such as is adopted for locomotives and large rail cars. It is seen at once that the quantity of heat carried away

TABLE 1 HEAT BALANCE OF A DIESEL ENGINE DEVELOPING 1000 BHP AT 700 RPM WITH BÜCHI TURBO-CHARGING. LOAD VARYING WITH CONSTANT SPEED

Brake mean effective pressure, lb sq in.	120		105		81		53	
Heat Balance	Per cent	Btu per bhp-hr	Per cent	Btu per bhp-hr	Per cent	Btu per bhp-hr	Per cent	Btu per bhp-hr
Effective work	38.1	2505	37.9	2505	37.1	2505	35.0	2505
Heat losses:								
Cooling water for engine	16.1	1057	16.2	1072	17.2	1168	17.0	1210
Cooling water for oil-cooler	2.3	151	2.6	171	3.1	210	4.1	294
Cooling water for turbine	2.2	143	2.3	151	2.0	135	1.7	123
Heat in exhaust gases after turbine	36.6	2415	34.9	2315	35.6	2405	34.1	2445
Other heat losses	4.7	322	6.1	417	5.0	342	8.1	583
Total heat introduced with the fuel per bhp-hr	100.0	6593	100.0	6631	100.0	6765	100.0	7160

in the cooling water per brake horsepower-hour is much less than in an ordinary Diesel engine working without supercharging. With this engine it is assumed that a water-cooled exhaust-gas turbine is used. Water cooling is recommended for large exhaust-gas turbines, i.e., when they are not limited in weight as those used for small high-speed engines and airplane engines. The heat loss for cooling the turbine is very small; little more than 2 per cent of the heat introduced into the engine. Also in the oil cooler of the engine, only 2.3 to 4.1 per cent is carried away, depending on the load. This quantity of heat is a direct measure of the work done in overcoming friction in the supercharged engine, which friction is again responsible for wear in the engine. About 36.6 to 34.1 per cent of the heat passes away in the exhaust from the turbine.

The figures given allow conclusions to be drawn regarding the dimensions required for the coolers for cooling water and lubricating oil and regarding possible further utilization of the heat in the exhaust gases.

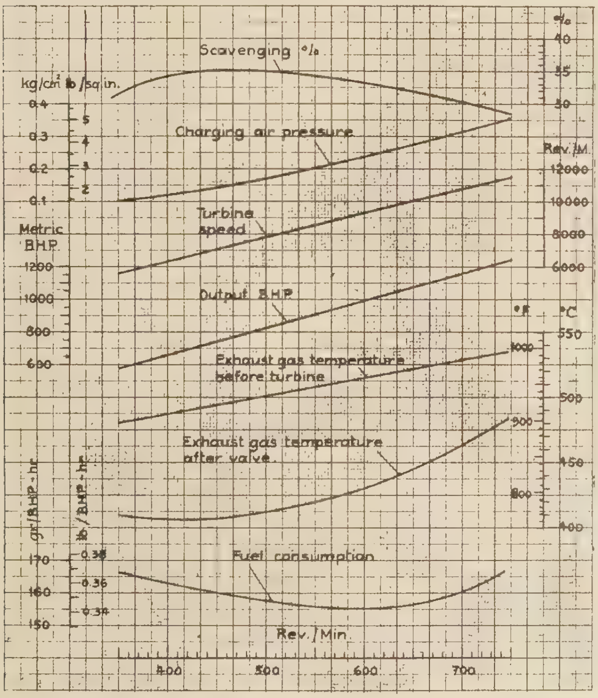

Fig. 20 Test Results When Running a Turbo-Charged Diesel Engine Under Constant Torque but at Different Speeds

Behavior With Variable Speed and Constant Torque of the Engine

Fig. 20 shows the conditions when the engine was working constantly with a mean effective pressure of 132 lb per sq in. with the speed varying from 750 to 350 rpm. Fig. 20 shows that, as the speed decreases, the fuel consumption per brake horsepower-hour and the temperatures after the exhaust valves and ahead of the turbine fall to a certain minimum. This minimum for the fuel consumption is 0.342 lb per bhp-hr, while the temperatures reach their minimum at 420 rpm. The speed of the turbine falls linearly as also does the charging pressure after the blower. The pressure has a tendency to fall less at speeds under 400 rpm (which are very low for the engine), since the temperature of the exhaust gases then increases as a result of increased fuel consumption.

We see, therefore, that a supercharged engine can maintain the normal torque down to a greatly reduced speed, without the temperatures and fuel consumption attaining excessive values. This fact depends on the time area for the passage of scavenging air. In spite of the falling charging pressure it is possible to maintain the same temperature conditions down to about 40 to 45 per cent of maximum speed. As tests have shown, the same holds also for comparatively slow-running stationary and marine engines.

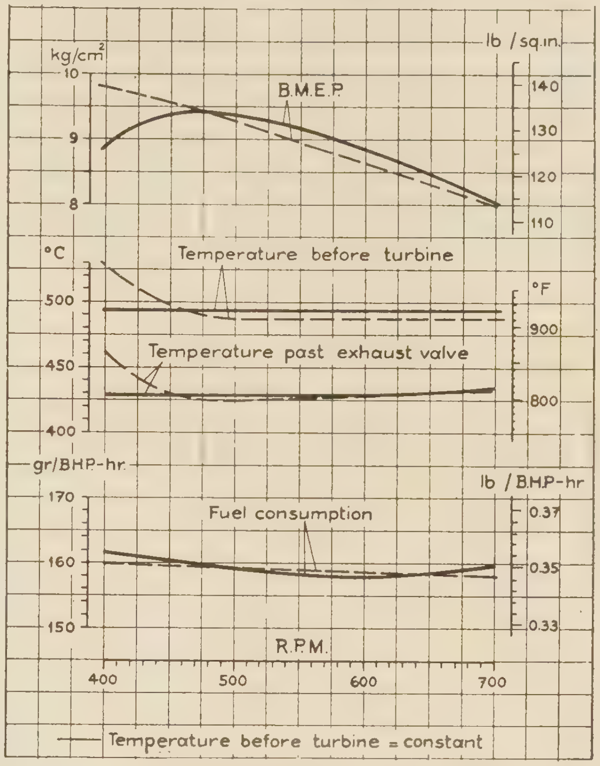

Fig. 21 Test Results When Running a Turbo-Charged Diesel Engine With Constant and Slightly Increasing Exhaust Temperatures at Different Speeds

Torque Obtainable With Constant Exhaust Temperatures and Variable Speed

Fig. 21 shows that when reducing from maximum speed to under 70 per cent and maintaining the same exhaust-gas temperatures, the torque can be increased by about 18 per cent. It is evident that exhaust-gas turbo-charging provides very favorable conditions. These conditions are particularly important for traction engines, where the speed of the engine falls when taking a gradient or when accelerating. If the torque of the engine can be increased as shown, the acceleration of the vehicle and the taking of gradients will be facilitated.

Conditions are also illustrated in Fig. 21 for a certain rise of exhaust temperatures with decreasing speed of the engine. As can be seen, the torque can be increased by about 23 per cent when reducing from 700 to 400 rpm.

Influences of the Automatic Change in the Charging-Air Pressure

Exhaust-gas turbo-charging provides an advantage in that the charging compressor is not coupled to the internal-combustion

engine, also, that it adjusts itself independently of the engine. It runs at different speeds, depending on the load of engine. When starting, and when speed or load of engine is low, practically no charging pressure is produced. Consequently, no adverse influence will be exerted, as for example in the case of charging blowers mechanically coupled to the engine. When starting, and at low loads, the latter require the same power to drive them as at high loads. Mechanically driven blowers therefore cause a very high fuel consumption at low loads. If the blower is taken out of service, complicated clutch couplings must be provided. On the other hand, with exhaust-gas turbo-charging, the charging pressure varies and increases when the load or the speed of the engine increases. This is of special importance for overload conditions. If such an engine is overloaded, for example by 20 per cent, the quantity of air introduced into the engine will also be increased by at least 10 per cent because the charging pressure is automatically increased. The increase in load on the engine is in reality only 10 per cent, in respect to the weight of air available. This is also the reason why the fuel consumption and the exhaust-gas temperatures do not rise so quickly in the overload period as in ordinary engines without exhaust-gas turbo-charging or with mechanically driven blowers. It must be remembered that, as shown in Fig. 3, the quantity of scavenging air is also increased.

Other points in connection with exhaust turbo-charging could be mentioned. It ought, however, still to be noted, that because of the much smaller moving masses in a supercharged engine, the inertia effect of the masses is much reduced. A further important point, particularly for high-speed and multicylinder engines, is that the broadening of the indicator diagrams of the working cylinders (which is equivalent to less pronounced changes in pressure) means less pronounced torsional oscillations in the crankshaft, the amplitudes being reduced to one half or less of those in ordinary Diesel engines with acute indicator diagrams.

Performance of Lubricants Based on Diesel-Engine Service Conditions

By C. M. Larson,[1] New York, N. Y.

The author discusses the effects of Diesel-engine design and operating conditions on the performance of lubricants used in these engines. He presents charts which can be used to select the proper lubricant for definite operating conditions of Diesel engines, and gives an example showing how to use one of the charts.

In judging the performance of lubricants used in solid-injection Diesel engines, there are certain definite designs and operating conditions imposed on the lubricant which have to be considered. It is necessary, therefore, to take current design requirements and study the service effects on the lubricating oil. The lubricating system of today is of the dry sump type, one pump circulating oil to the bearings and cylinders and another suction pump returning the oil to the supply tank. The same oil, therefore, lubricates the bearings and the power cylinders.

First consider how the viscosities of lubricating oils are being classified by various Diesel-engine manufacturers. In the majority of designs, the viscosity requirements are 400 to 780 sec Saybolt Universal at 100 F, as shown by area *A* in Fig. 1. Winton, however, is restricting their circulating oils to area *B*, which is limited by 1000 sec viscosity at 100 F maximum, and 75 sec at 210 F minimum.

The oils covered by area *A* consist of those ranging from Gulf Coast, through Mid-Continent, Mid-Continent solvent-treated, to Pennsylvania, while area *B* is comprised of selected Mid-Continent, Mid-Continent solvent-treated, Pennsylvania, and Pennsylvania solvent-treated oils. Winton leans toward the use of Pennsylvania oil of 85 to 95 sec viscosity at 210 F, with the 1000 sec viscosity at 100 F maximum maintained.

Fig. 2 shows the most modern design of the Hooven, Owens, Rentschler double-acting, four-stroke-cycle Diesel engine, for which is specified oils having a viscosity of 450 to 550 sec at 100 F. This Diesel engine was tested and accepted using a Gulf Coast oil of 500 sec Saybolt Universal viscosity at 100 F, which oil falls in zone 7 of Fig. 1.

Fig. 3 shows the Winton two-stroke-cycle Diesel engine tested using a Pennsylvania oil with a viscosity of 85 sec at 210 F, which oil falls in zone 1 of Fig. 1.

Atlas Method of Selecting Lubricating Oils

One of the most complete methods for the selection of the grade or viscosity of the oil for various types of service and temperature conditions, without respect to quality, is the lubrication chart shown in Fig. 4. This chart was developed by the Atlas Imperial Diesel Engine Company. The selection of the lubricating-oil quality is left to the customer or the oil-company engineer who is acquainted with the actual operating conditions.

The margin of the chart adjacent to the temperature-difference values has been arranged in zones, with subzones *A*, *B*, and *C* which are used in conjunction with the engine-room temperature for indicating the proper oil grades. The various S.A.E. numbers or grades with corresponding viscosities appear as diagonal bands across the chart and have been correlated with the other values to insure the selection of an oil with the correct viscosity for the conditions encountered. Engine recommendation sheets, similar to Table 1, are used by Atlas Imperial Diesel Engine Company to furnish complete engine data including the speed on which the oil recommendations are based and the proper zone in which the engine is located for the conditions indicated. Standard Atlas engines are not equipped with oil coolers and are assumed to be supplied with cooling water at the average temperature found in practice. Stationary and industrial-engine sheets, as shown by Table 1, include zone recommendations for radiator cooling systems, in which case it is assumed no oil cooler is employed. Intermittent duty covers engines operating at intermittent loads and speeds, such as found in installations in power shovels, draglines, locomotives and power units. Table 1 lists various models of Atlas engines and shows the lubrication zones in which each standard engine, and standard engines with oil coolers and radiator cooling systems, are located. The recommended lubrication zone is based on the operation of the engine at continuous load and speed, except where specifically indicated otherwise. The lubrication zones are definitely defined for each engine under the conditions specified in the engine recommendation sheets.

TABLE 1 STATIONARY FOUR-CYCLE ATLAS DIESEL ENGINES AND LUBRICATING ZONES IN WHICH THEY ARE LOCATED

Engine characteristics						Lubricating-zone classification			
							Special oil cooler (accessory)	Radiator cooling system	
Model no.	Hp	Cylinders	Bore, in.	Stroke, in.	Speed, rpm	Standard engine		Maximum duty	Intermittent duty
4ES327	80	4	7	8.5	650	3*A*	1*B*	3*B*	3*A*
6ES327	120	6	7	8.5	650	3*A*	1*B*	3*B*	3*A*
3HS1021	105	3	10	13.0	360	2*B*	1*B*	2*C*	2*B*
4HS1021	140	4	10	13.0	360	2*B*	1*B*	2*C*	2*B*
6HS1021	210	6	10	13.0	360	2*C*	1*B*	3*A*	2*C*

In selecting the proper grade of lubricating oil for a given engine, first secure the correct zone from the recommendation sheets. Knowing the engine-room temperature, the S.A.E. number can be found from Fig. 4 by locating the intersection of the vertical temperature lines with the horizontal zone. If the oil temperature to the bearings is known or can be determined, the S.A.E. number may be selected from this temperature alone since the oil-temperature lines are parallel to the grade bands.

---

[1] Supervising Engineer, Sinclair Refining Company, New York, N. Y. Mem. A.S.M.E. Mr. Larson received the degree of B.S. in M.E. from Armour Institute of Technology in 1913. He became lubrication engineer with the Texas Company in Chicago, and was advanced to the position of chief engineer in charge of lubrication-service engineers, comparative tests, lubrication-equipment installation, and development of new products. He served as wing lubrication officer, first lieutenant, Air Service, U. S. Army. In 1919 he joined the Sinclair Refining Company as assistant supervising engineer and became supervising engineer in 1921.

Contributed by the Oil and Gas Power Division and presented at the National Oil and Gas Power Meeting of The American Society of Mechanical Engineers held at Ann Arbor, Mich., June 24 to 27, 1936.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until April 10, 1937, for publication at a later date. Discussion received after the closing date will be returned.

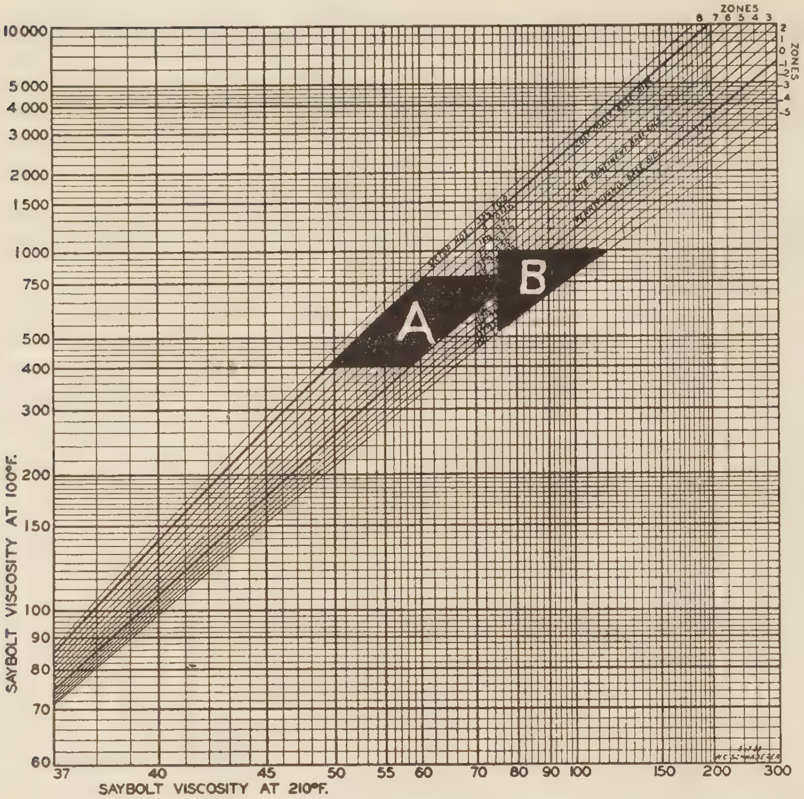

Fig. 1 Straight-Line Viscosity-Zone Index Chart

Wherever possible the S.A.E. number should be selected on the basis of the oil temperature to the bearings, although in the majority of installations it will be difficult or impractical to determine this temperature, and the grade must of necessity be selected on the basis of the lubrication zone and the engine-room temperature. When an accessory oil cooler (not manufactured by Atlas Imperial Diesel Engine Company) is incorporated in the engine lubrication system and the oil temperature is unknown, it will usually be safe to assume the temperature to be 10 to 15 F above the water inlet temperature to the cooler. An oil of a given S.A.E. number may be safely used at temperatures 10 F above and below its boundary on the chart. In case of doubt, it is advisable to use a heavy rather than a light lubricating oil.

As an example, select the proper grade of lubricating oil for a Standard Atlas Model 6ES327, 120-hp, six-cylinder, $7 \times 8^1/_2$-in., 650-rpm stationary engine, operating at an engine-room temperature of 80 F. It is seen from Table 1 that an oil falling in zone 3*A* should be used with this engine. Referring to Fig. 4 the intersection of zone 3*A* and the vertical 80-F line indicates an S.A.E. number of 50. An S.A.E. 50 oil may be safely used in engine-room temperatures of 40 to 100 F.

Effects of Operating Conditions on Lubricating Oils

In circulating systems, oil escapes from the bearings and is whipped into a fine spray. The hotter the oil and the more it is whipped into the hot air or blowby gases, the greater the oxidation and sludging of the oil. The rate of oil circulation and capacity of the system regulates the amounts of heat absorbed or removed. Naturally, an engine, with a rated capacity of 1 gal per 6 hp, with the same rate of circulation and operating conditions, will impose less hardship on the oil than the same engine with a capacity of 1 gal per 10 hp. In several instances, where it was impossible to increase oil capacity, excessive sludge trouble was eliminated by increasing the rate of circulation and installing an oil cooler. The increased rate of circulation of cooler oil reduced the piston and ring temperatures so that less oxidation and cracking of the oil occurred and the blowby was reduced because a better piston seal was maintained. Formerly, heavier oils were tried but the condition became worse because of the higher temperatures and the more sluggish oil flow.

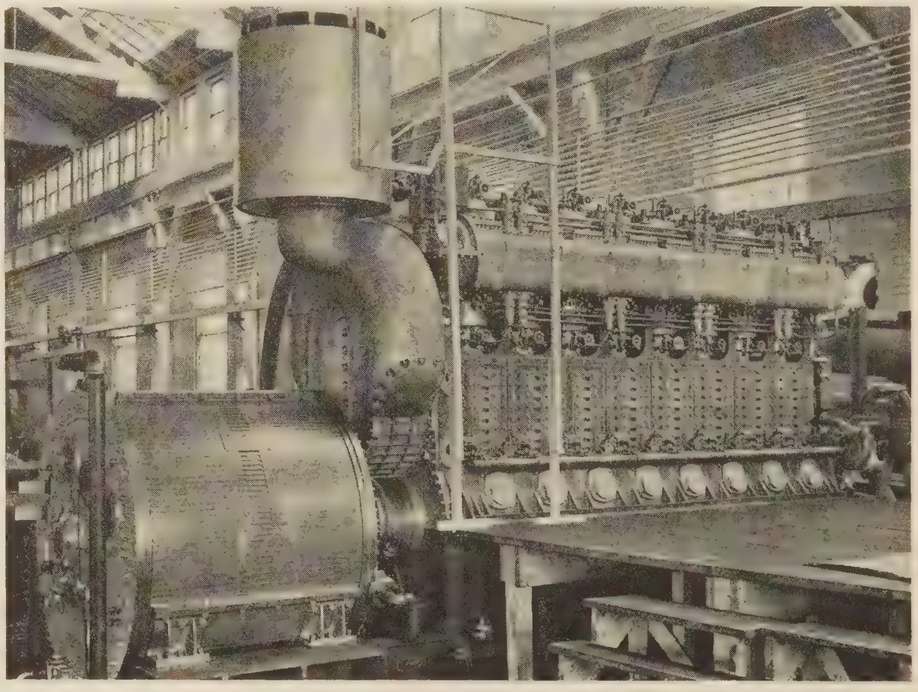

Fig. 2 Modern Hooven, Owens, Rentschler Double-Acting Four-Cycle Diesel Engine

High end-point, high carbon content, or low ignition quality in a fuel has a great deal to do with excessive sludge in the lubricating oil. This is due to slow or faulty combustion and cracking of the heavy ends.

Fig. 5, showing a plot of spontaneous-ignition temperature against the average boiling point of different fractions of petroleum oil, indicates theoretically the drastic change in characteristics of the heavy fractions of a petroleum distillate at different ignition temperatures. The sharp turn of the curve at 700 F indicates that such fractions do not burn completely, and that they crack into fine carbon which blows by the pistons into the circulating oil.

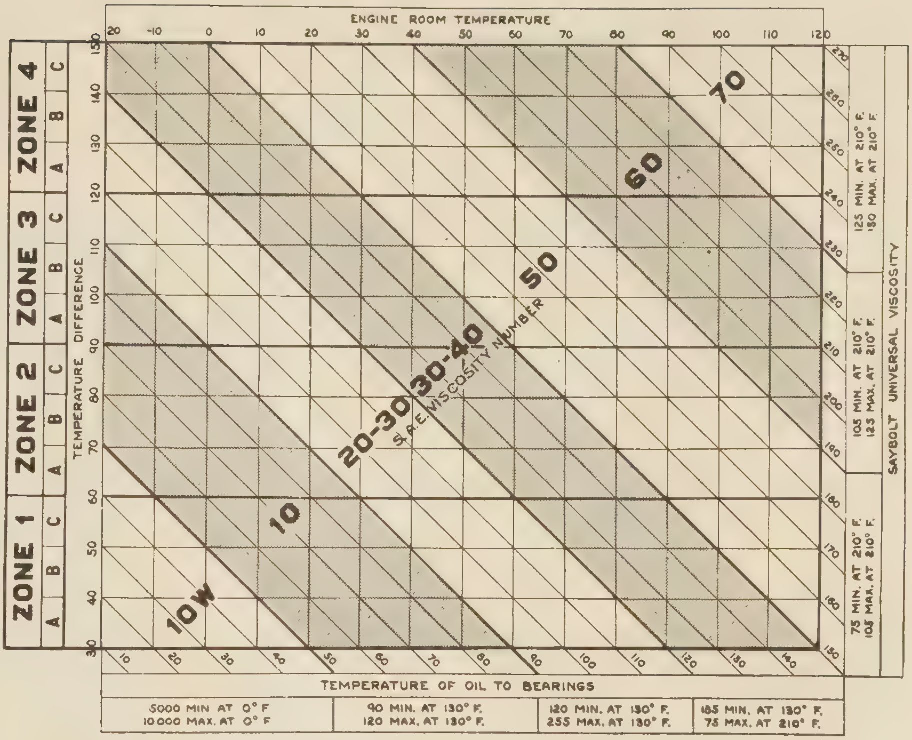

Fig. 4 Lubrication Chart Developed by the Atlas Imperial Diesel Engine Company

In addition to this, consider the high pressure shown in Fig. 6*d* that was caused by a fuel with poor ignition qualities. The fuel had a cetane number of 31. It caused rough running, and raised the maximum pressure to 1059 lb per sq in. at full load, or 262 lb per sq in. higher than the maximum pressure shown in Fig. 6*b*, which was attained with a fuel having a cetane number of 57. The part-load maximum pressure of 862 lb per sq in. attained by the fuel with a low cetane number and shown in Fig. 6*c* was also greater than the full-load pressure of 797 lb per sq in. attained with the better grade of fuel and shown in Fig. 6*b*. Because of these high pressures attained with low-quality rough-running fuel, the blowby with such a fuel is increased considerably, and where this condition is coupled with high end-point, much soot passes the piston rings into the crankcase. Where the shocks were too great because of high pressures attained with low-quality fuels, the bearings have been known to pound out.

An analysis of a circulating oil, complained of as giving bearing trouble, showed by the volume method that it contained 98.5 per cent oil, and 1.5 per cent sludge. When the oil was separated completely by a 6000-rpm centrifuge,[2] it virtually reverted to its original state, showing a viscosity of 520 sec at 100 F; a viscosity of 56 sec at 210 F, a neutralization number of 0.13 mg KOH; no precipitation number; a carbon residue of 0.10, and no ash content. However, an analysis of the 1.5 per cent sludge revealed that it contained 10.33 per cent oxidized oil (asphaltic) by weight, 8.8 per cent iron oxide, 11.37 per cent iron sulphide, 69.5 per cent carbon (piston blowby), and that it had an acid reaction to water.

The examination of the fuel showed that the sludge was

[2] "Lubricating Oil—General Information, Requirements and Methods of Test," Bulletin N. Eng. 31, 1936, Bureau of Engineering, U. S. Government Printing Office, Washington, D. C.

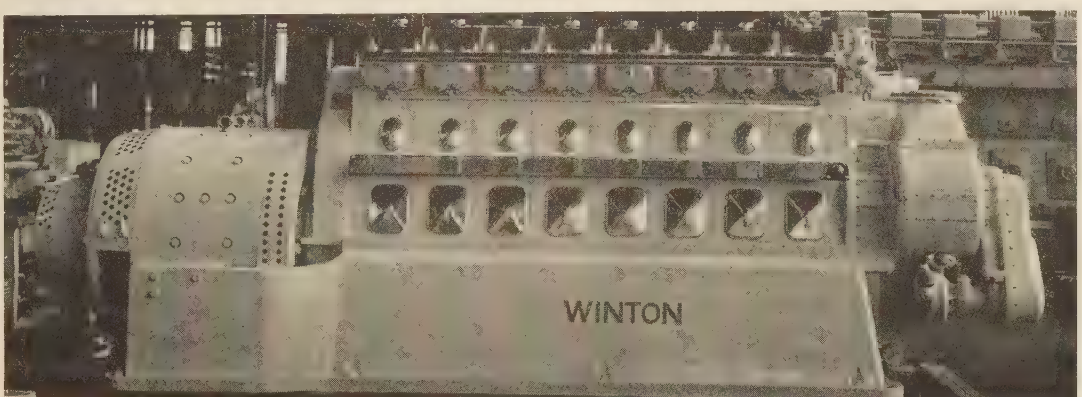

Fig. 3 Winton Two-Cycle Diesel Engine

caused by the 730 end-point and 37 cetane number, and that the high acid and iron sulphide were caused by the high sulphur content of 1.51 per cent in the fuel. When the fuel was changed to a 600-end-point product with a low sulphur content of 0.25 per cent and a 55 cetane number (the engine operating at 900 rpm) the bearing trouble disappeared and the sludge condition was greatly reduced even though the drainage periods were greatly extended.

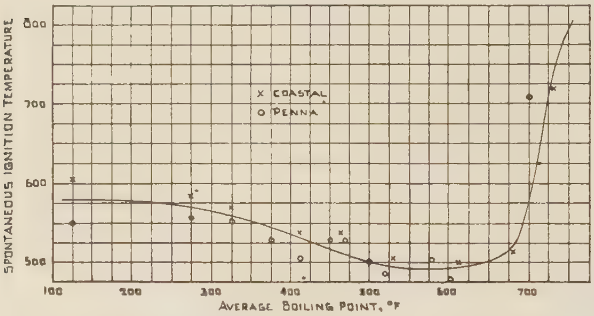

FIG. 5 EFFECT OF SPONTANEOUS-IGNITION TEMPERATURES ON GULF COAST AND PENNSYLVANIA PETROLEUM DISTILLATES

The viscosity of the circulating oil increases with use due to oxidation. Dilution never occurs except where the fuel injection plungers are tied into the circulating oil system, and plunger leakage takes place.

Every precaution should be taken to prevent the entry of water into the circulating systems. Water in the oil not only increases the frictional resistance, causing the oil film to break down prematurely, but also corrodes the journals.

Excessive carbon deposits in piston-ring grooves interfere with the functioning of the rings. The rate of deposit varies with each particular engine. Carbon deposits of this nature can be reduced by preventing the aggregate of carbon from forming. This can be best accomplished by keeping the temperature of the pistons below the cracking point of the oil and allowing enough lubricating oil to pass the top ring to flush the blowby carbon

TABLE 2 WEAR OF LINER OF A DIESEL-ENGINE CYLINDE

Distance from top of piston, in.	Longitudinal wear per 1000 hr, in.	Transverse wear per 1000 hr, in.

from the ring grooves. However, the high end-point of the fuel, which is slow-burning and cracks into fine sooty carbon and tarry matter, will increase the rate of ring sticking. In a few instances, where the temperature of the rings was high enough to crack the lubricating oil, or even where circulating-oil temperatures were extremely high, ring sticking was overcome by the addition of a small amount (2 per cent or less) of carbon-disintegrator material to the lubricating oil. This kept the carbon aggregate from building up into a briquette. It is too early to say how extended this additional agent will be used in large industrial Diesel engines.

Leakage of the gases past the split of each piston ring, and especially past the clearance between each ring and its groove, causes pressure to build up behind the rings. Behind the top ring this pressure is greatest, being approximately 100 per cent of the pressure on the piston. The pressure behind the second ring is approximately 80 per cent of the pressure on the piston. Behind the last ring it is practically negligible. The upper rings produce a squeezing action which greatly reduces the oil film. The lubricating film on the upper portion of the cylinder wall is subjected to higher temperatures for longer periods in addition to high ring pressures, and therefore this top portion of the cylinder wears the fastest. This is clearly shown by the measurements of a high-speed Diesel-engine liner given in Table 2.

Performance of lubricants in Diesel engines is so interrelated with combustion efficiency and lubricating-oil stability, that it is difficult to isolate them. However, in so far as the lubricating oil can be considered a contributing cause, if a lubricant is used which resists to the greatest degree possible any change in viscosity, carbon content and acid number during operation, then the user is assured that troublesome asphaltenes will not develop to cause sludging in the crankcase and sticking of piston rings and valves.

Rotary Drilling Rigs Operated by Internal-Combustion Engines

By D. M. MacCARGAR[1] and O. A. HAAS,[2] TULSA, OKLA.

The authors discuss the use of internal-combustion engines as prime movers for rotary drilling rigs. They show diagrammatically the advances made in the application of internal-combustion engines to rotary drilling, and the different methods of connecting the engines through mechanical and electrical means to the drilling equipment.

THE PRACTICAL advantages of the internal-combustion engine have led to its adoption as a prime mover for rotary drilling rigs. The basic reasons for their general acceptance are (1) a great saving in fuel costs when compared to steam-driven units, (2) an equal saving in water, and (3) their portability which shows up in the form of lessened transportation costs. It is the intention of the authors to show by means of line diagrams and sketches the evolution or the development of the use of internal-combustion engines for rotary drilling. This is to be accomplished by showing the different methods of connecting the engines through mechanical means to the drilling equipment, and later by showing the more flexible methods in which electric generators and motors are used as part of the drilling units.

In the following paragraphs wherever the designation "mechanical drive" is used in a description, it is to designate a rotary rig driving the machinery direct from internal-combustion engines using either V-belts, chains, or gears as power-transmission mediums. Where "electrical rig" is referred to, it will mean either a direct- or alternating-current rig with internal-combustion engines driving the generators and either direct- or alternating-current motors driving the machinery.

Certain definite requirements are necessary in the design of a mechanical rig. The most important of these is that the connection between the engine and the load be elastic in nature. To obtain the maximum efficiency and allow the driller to operate his engines at their best torque point, it is necessary that a sufficient number of speed changes be provided in the design. In direct-current electric drives, due to the inherent characteristics of the equipment, it is not necessary that much thought be given to the type of draw works or the speed changes available, although with alternating-current electric drives the condition is almost comparable with mechanical drives.

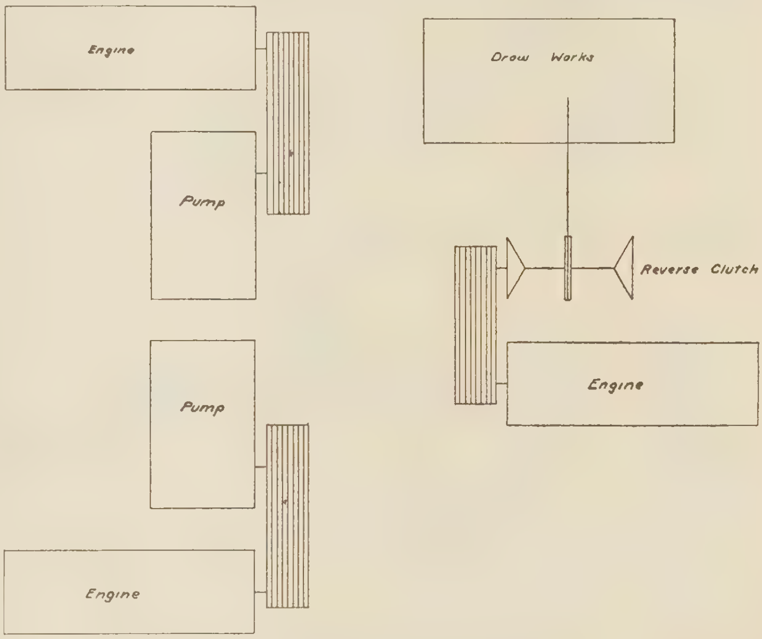

Fig. 1 First Successful Arrangement for Driving Rotary Drilling Rigs With Internal-Combustion Engines

Probably the first rotary rig driven by an internal-combustion engine, mechanically operated, was installed in California in 1924. Owing to the lack of knowledge in the design of proper reversing clutches, this rig was converted about a year later to a full direct-current electric drive. After a lull of about two years, during which time very little work was done on the design of rigs for rotary drilling driven by internal-combustion engines, an installation was made in 1927 of a mechanical rig in the Mid-Continent territory. This was probably the first successful rig of its type. A layout of this rig is shown in Fig. 1. In this layout it will be noted that the application of the engines to rotary-drilling equipment follows along the conventional line of steam practice; that is, an individual prime mover was provided for each pump and for the draw works. With this arrangement when engine trouble was encountered, particularly on the draw-works engine, it was necessary to halt the operations until the draw-works engine could be repaired or move one of the pump engines to the draw-works engine position. It might be well to note in passing, the prior attempts to connect in-

[1] District Manager, Allis-Chalmers Manufacturing Co. Mr. MacCargar was educated in Canada. He entered the employ of the Allis-Chalmers Company in Toronto in 1907, and with the exception of a period during the War and a short period on other work he has been associated with the Allis-Chalmers Manufacturing Company since that time. For the past fifteen years he has been active in the oil industry, specializing in drilling design and application of rotary drilling equipment.

[2] Chief Engineer, Oklahoma Iron Works and International Supply Company. Mr. Haas received the B.S. degree in 1926 and the M.S. degree in 1928 from the University of Wisconsin. He was employed as an engineer and sales engineer with the Allis-Chalmers Manufacturing Company for 21 years, but resigned in 1936 to assume his present position.

Contributed by the Petroleum Division and presented at the Semi-Annual Meeting of The American Society of Mechanical Engineers held at Dallas, Texas, June 15 to 19, 1936.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until April 10, 1937, for publication at a later date. Discussion received after the closing date will be returned.

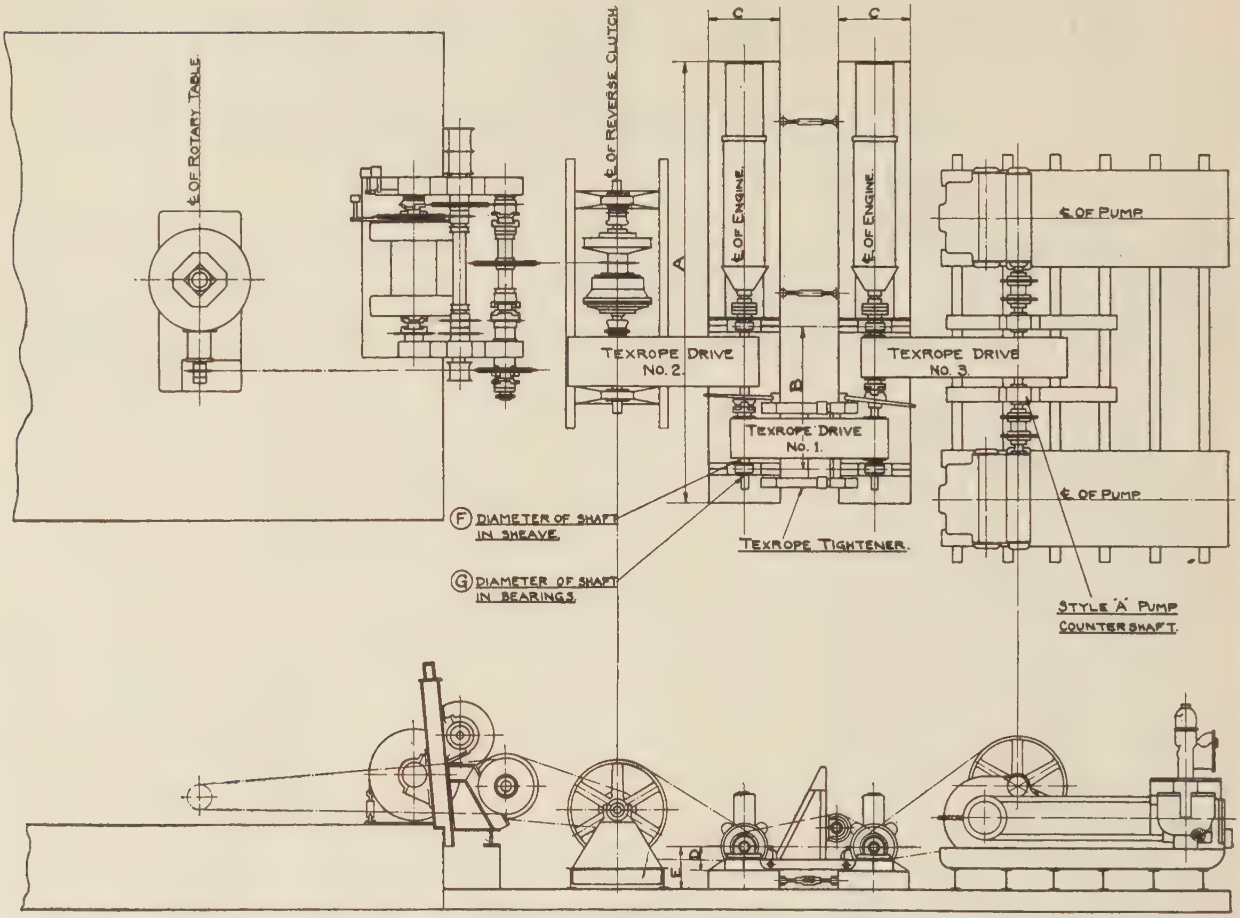

Fig. 2 Application of Internal-Combustion Engine to Rotary Drilling Rig for Eliminating Shutdowns Due to Failure of the Draw-Works Engine

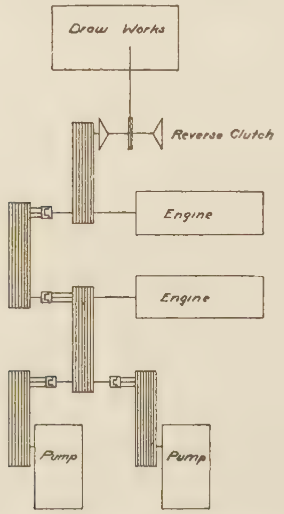

Fig. 3 A Modification of the Arrangement Shown in Fig. 2

ternal-combustion engines to the drilling equipment had employed the use of chains or gears. At the time this rig was designed, V-belt drives were coming into prominence and their use as a flexible power-transmitting medium was really a prime factor in the success of this rig. As stated before, the main objection to this rig was the danger of rig shutdowns from engine trouble and this gradually led to the development of the layout as shown in Fig. 2.

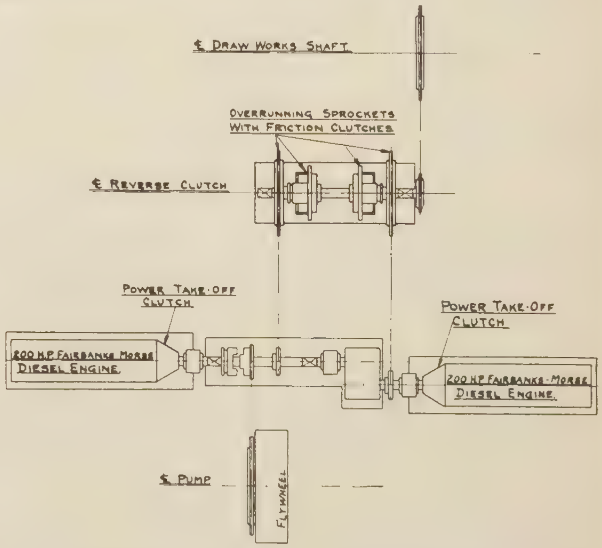

Fig. 4 Arrangement of Two Engines Face to Face to Provide Effective Reversing of the Draw Works

This mechanical drive provides the flexibility of either individual engine or combined engine operation by means of clutches arranged on the power stub shafts connected to the engine. Normal drilling operations are performed by one engine driving the draw works and table, while the other engine drives the pumps. For hoisting duty the two engines are compounded by means of clutches and the total power is then applied to the draw works. If either of the engines should be down, the other engine can continue the work by proper manipulation of the clutches. In some cases where the proper speed changes are not provided for on the draw works, correct drilling speeds may not be obtained when referred to a predetermined pump speed or vice versa, but conditions are so closely approximated that progress is not greatly hampered. There are many modifications of the installation shown in Fig. 2, one of which is shown in Fig. 3 which shows a different method of driving the pumps.

One of the major objections to the mechanical rig has been the complications introduced in the design of a good reliable reverse clutch. In most cases these clutches had to be designed with planetary or bevel gears. Fig. 4 shows a layout that utilizes

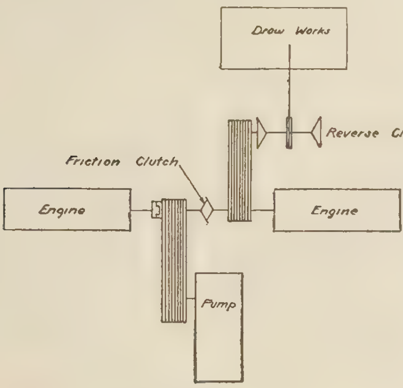

Fig. 5 Another Arrangement for Obtaining Effective Reversal of Draw Works

two shafts operating in opposite directions. To obtain the reversal on the clutch two engines are connected together face to face through a 1-to-1 gear arrangement. Opposite sides of the reverse mechanism are connected to opposite rotative shafts. It will be noted that provision is made for disconnecting the pump drive by means of a jaw clutch. Any of the methods shown in the preceding sketches for double pump drive could be used with this arrangement.

Apparently the wide use of the design shown in Fig. 4 led to the arrangement shown in Fig. 5. Here a right-hand and a left-hand engine are connected together by means of a friction clutch. Under ordinary operation the friction clutch is disengaged, one engine driving the pump and the other engine driving the draw works. It will be noted that there is a jaw clutch provided to disconnect the pump. For hoisting operations the friction clutch is engaged and the power of the two engines is used in multiple for hoisting.

There are a great many modifications possible in mechanical drilling rigs. These modifications are perhaps based on the availability of material, the connection of the designer, and the whim of the user. An example as to how far this can go is shown in Fig. 6 wherein a number of speeds are provided in the power-transmission mechanism, and in which both gears and chains are used. In the power transmission itself there are three speeds which means that with a four-speed draw works there would be twelve hoisting speeds and at least three drilling speeds.

As mentioned before, the limitations in torque characteristics

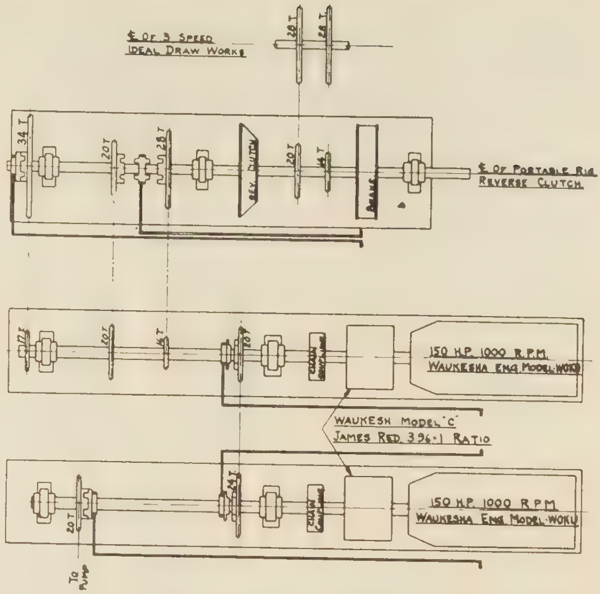

Fig. 6 Arrangement in Which a Number of Speeds Is Provided in the Power-Transmission Mechanism of Rotary Drilling Rigs

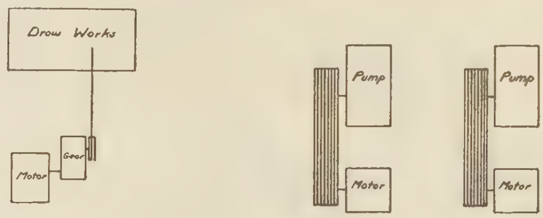

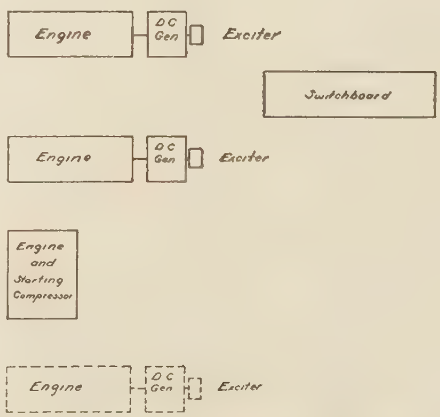

Fig. 7 Arrangement of First Direct-Current Equipment for Rotary Drilling Rigs

of internal-combustion engines at low speeds and their inability to handle shock loads led to the introduction of direct-current electric units as a transmission medium between the engines and the drilling equipment proper. On the first direct-current equipment built there was provided a direct-current generator

and a direct-current exciter direct-connected to each engine, and inasmuch as variable-voltage control or the Ward-Leonard system was used, if one engine broke down the whole drilling operation ceased, because it is necessary to have one generator for each motor. It is true that switching equipment was provided so that if one engine broke down it was possible to operate another engine for the hoisting operation to get the tools out of the hole. But still the drilling operation proper ceased until the drilling engine was back in service. This arrangement is shown in Fig. 7. The dotted lines show an improvement of the original development in which a reserve unit is provided with the improved scheme-switching equipment installed to allow any one of the engine units to be taken out and left out of service. It is apparent with this scheme that one of the three units is idle 100 per cent of the time, which means that there is an added investment for one reserve unit. As heretofore mentioned, most of the direct-current equipment in service today is based on the Ward-Leonard system of control, which means that a separate generator must be provided for each motor.

In drilling a well there are three distinct power requirements, as follows: (1) A variable-speed requirement for mud pump, (2) a variable-speed requirement for rotating the table, and (3) a heavy-duty hoisting operation. During ordinary drilling operations the first two are in use.

Limitations of the equipment shown in Fig. 7 led to the development of the arrangement shown in Fig. 8. The equipment shown in Fig. 8 includes one large and one small generator direct-connected to an engine; the small generator develops current for rotation and the large generator develops current for operating the slush pumps. Provision is made in the control for operating the two large generators together, either on the pump or on the

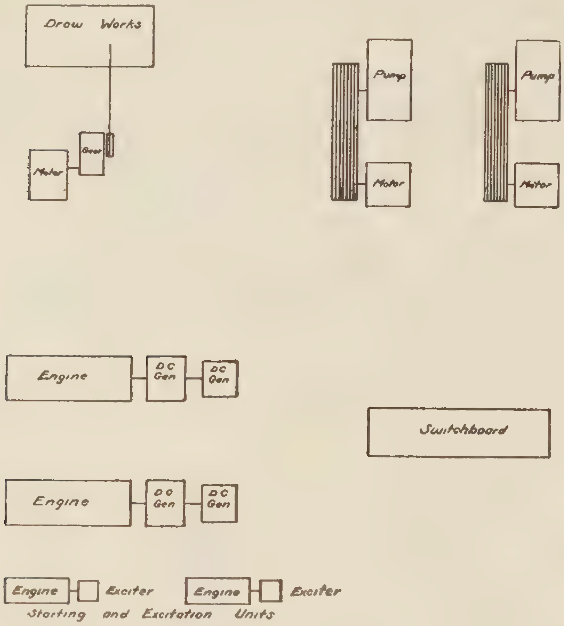

Fig. 8 Equipment Developed Because of Limitations of Arrangement Shown in Fig. 7

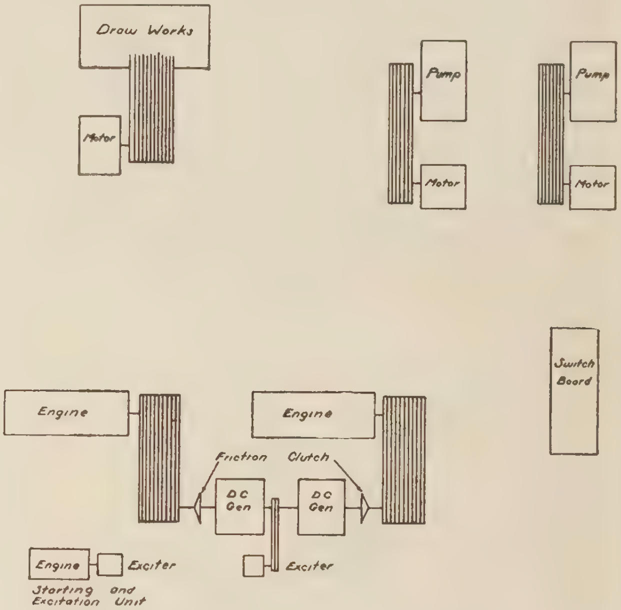

Fig. 10 Arrangement Permitting the Use of Engines of Any Speed With Stock Electrical Equipment

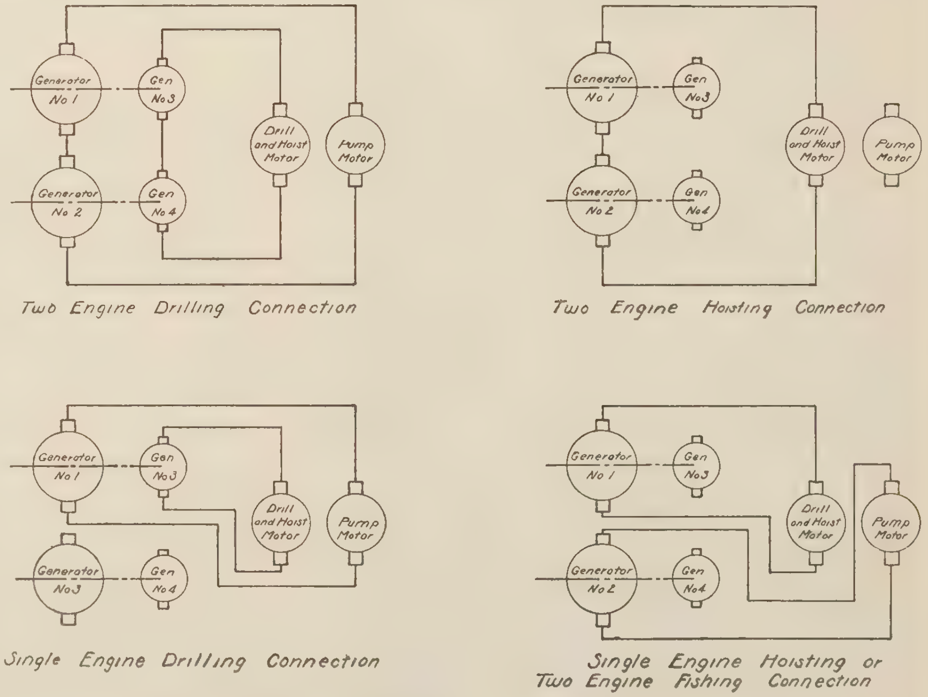

Fig. 9 Electrical Connections of Equipment Shown in Fig. 8

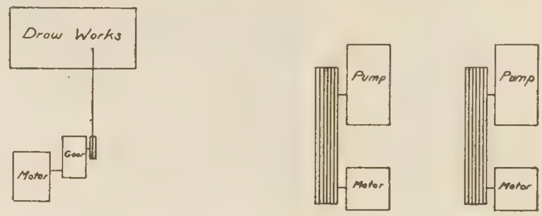
hoist, and the two small generators together for heavy-duty rotation. All operations are under full Ward-Leonard control. In this case if either engine breaks down the remaining engine can carry on the operations with full-speed control and with sufficient power to continue drilling without shutting down the operation. Most of the original units of this type were connected as shown in Fig. 9 in which the generators were run in series when both engines were in operation. Four different connections are shown. It will be noted that this is extremely flexible and all of the operations can be carried on with either one or two engines. Recently one manufacturer has offered a drilling unit which is identical with that shown in Fig. 8, with the exception that the generators are connected in parallel instead of series as shown in Fig. 9.

Because of the great range in ratings and speeds of the different types of Diesel and gas engines, and the fact that the drilling companies usually require stock shipments on their equipment, it was necessary to design a unit with which almost any speed engine could be used without expensive changes. In other words, a scheme that would allow the manufacturer of electrical equipment to build and stock drilling equipment, and allow the engine manufacturer to hook up to it readily, irrespective of the speed of the engines. The necessity of equipment of this kind led to the development of the arrangement shown in Fig. 10.



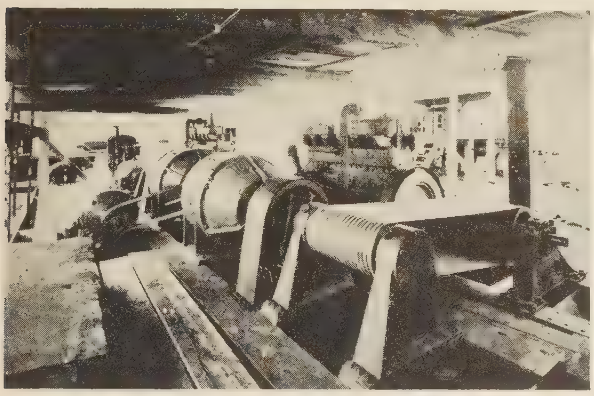


Fig. 11 Equipment Installed According to the Arrangement Shown in Fig. 10

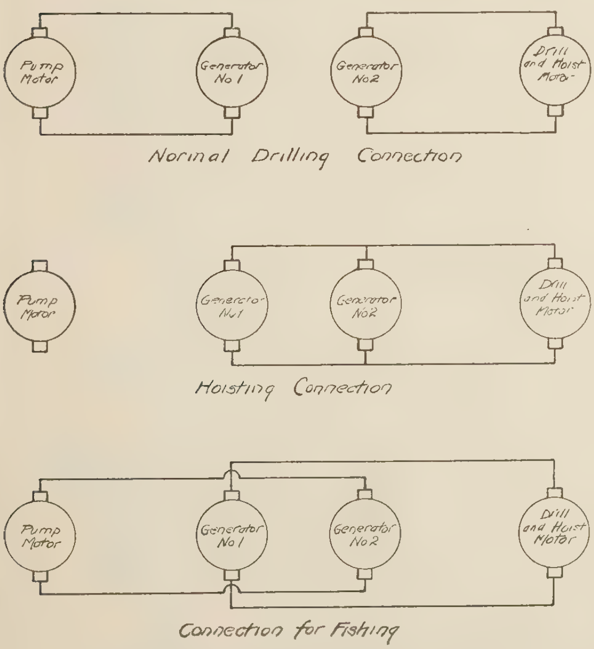

Fig. 12 Electrical Connections Used With Arrangement Shown in Figs. 10 and 11

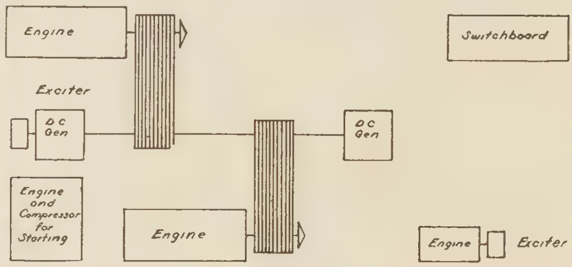

Fig. 13 Modification of Arrangement Shown in Fig. 10

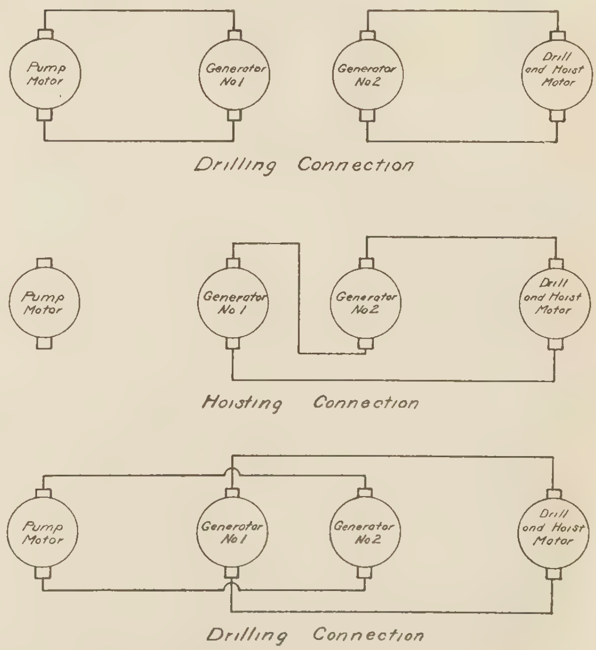

Fig. 14 Series Connections Used With Equipment Shown in Fig. 13

Note that two generators of different ratings are rigidly connected together and mounted on a common base and that the engines are connected to the generator shafts by means of V-belts. Any changes necessary to adapt engines of different speeds can be made by changing the pulley or sheave sizes. Provision is made

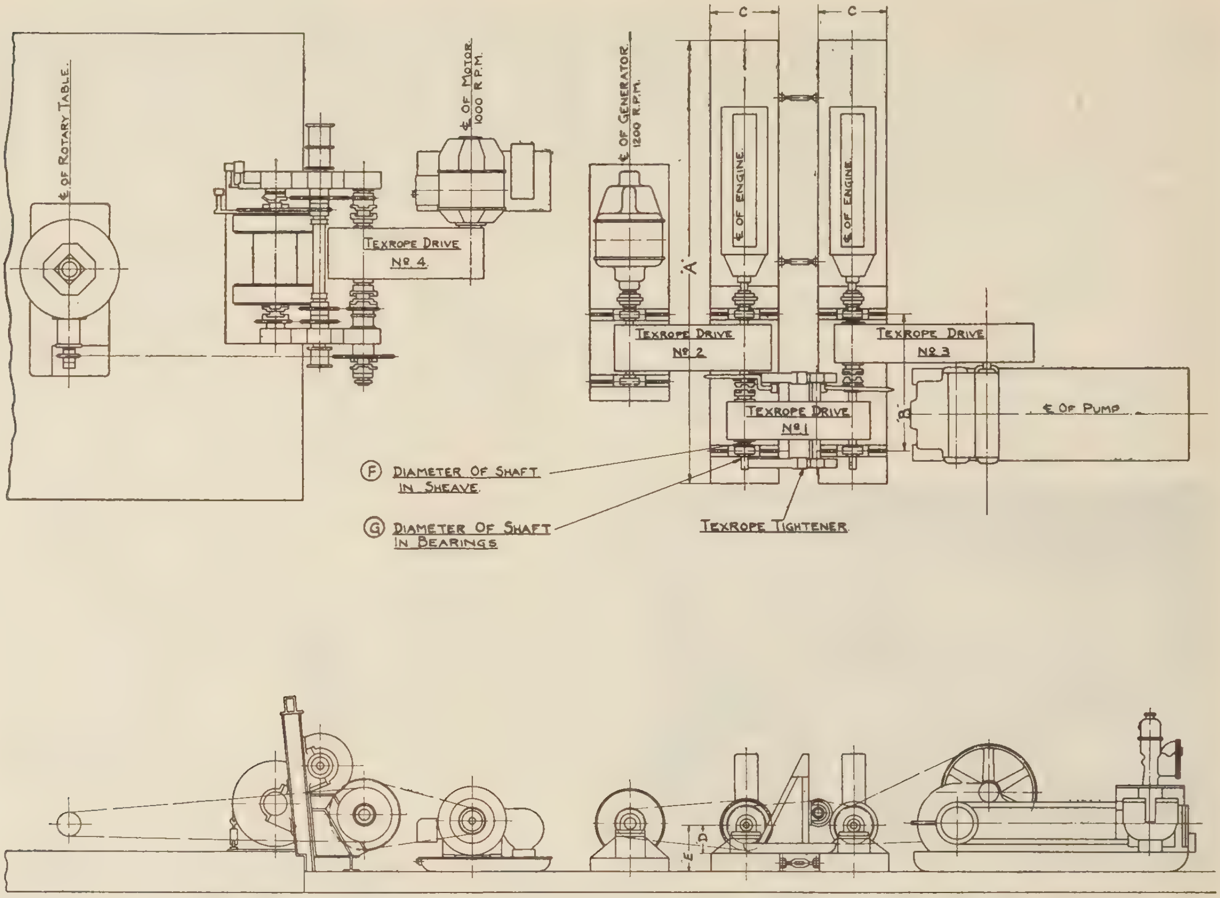

Fig. 15 Electrically Driven System Which Is Mechanically Similar to the System Shown in Fig. 2

by means of friction clutches to use either one or two engines. On original equipment of this type the parallel system of connection was used and still is in use by the manufacturer. The same manufacturer that built the equipment shown in Fig. 8, which uses the series system, built the equipment shown in Fig. 10 which uses the parallel system. The explanation of this is based on one of the fundamental laws of direct-current design, that is, the ease in which generators can be operated in series when connected to individual engines with irregular engine speed and the difficulty experienced in operating generators in parallel, when connected to individual engines where the speed is liable to fluctuate. In the scheme shown in Fig. 10, the generators are rigidly connected together by means of a solid coupling and the parallel system of connection is used because it is impossible for the generator speeds to get out of step. Slight irregularity in firing order or angular variation that might be present in the two engines is taken up in the elasticity of the V-belt drives. Fig. 11 shows a typical installation of the arrangement shown in Fig. 10. The connections for this system are shown in Fig. 12. Where it will be noted that the Ward-Leonard system is again used with an individual generator for each operation, and with the two generators in parallel for hoisting. In most of the systems built to date the control systems have been built almost entirely automatic in the respect that the setup or change in connections is accomplished by means of a small master drum at the driller's position. With this arrangement practically no hand switching is necessary.

A modification of the layout shown in Fig. 10 is shown in Fig. 13, the differences being in the mechanical arrangement of the

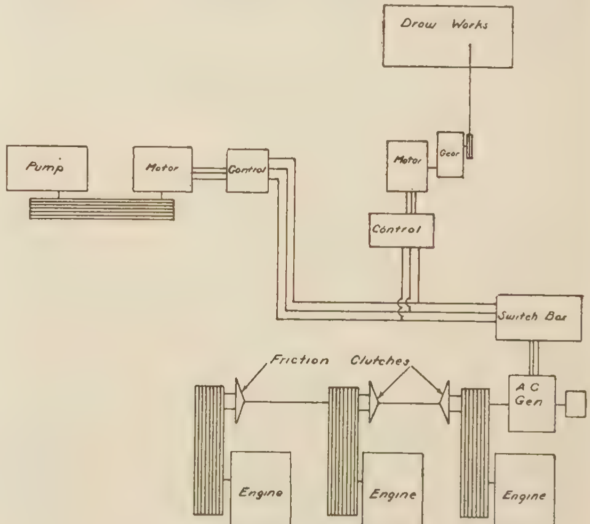

Fig. 16 Arrangement of Internal-Combustion Engines for Driving Alternating-Current Drilling Equipment

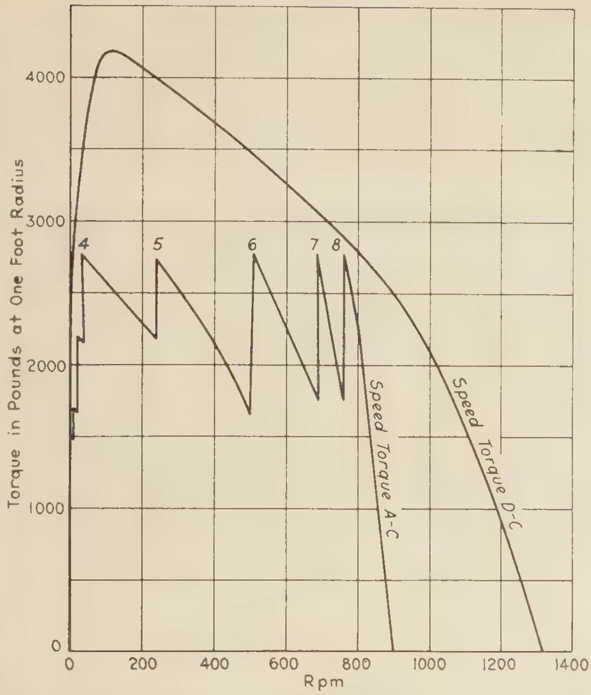

FIG. 17 TORQUE AVAILABLE WITH SAME GEAR RATIO AND SAME MAXIMUM ENGINE HORSEPOWER IN ALTERNATING- AND DIRECT-CURRENT EQUIPMENT

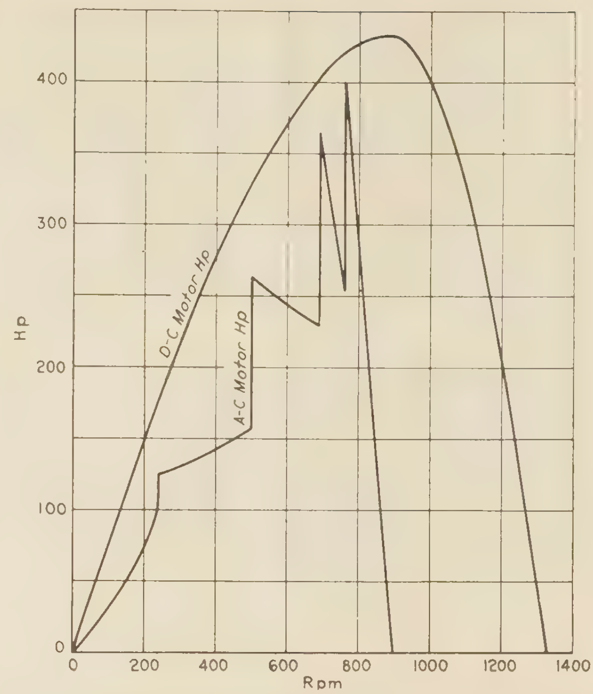

FIG. 18 USEFUL MOTOR HORSEPOWER WITH SAME MAXIMUM ENGINE HORSEPOWER IN ALTERNATING- AND DIRECT-CURRENT EQUIPMENT

engines and drives and the fact that provision is made for running the generators separately by the disengaging of an easily detachable coupling. Because of the fact that the engines can be and are run separately, the series system of electrical connection is used as shown in Fig. 14. Fig. 14 shows that for normal drilling operations separate generators are provided for both pump and drilling motors, while for heavy-duty hoisting two generators are run in series. This could be done either with the coupling engaged or disengaged. Because of the large differences in the power requirements between the table rotation and the mud pump, it is possible to use generators with a wide difference in ratings. In the hookup shown in Fig. 12, the ratings of the generators are additive, or in other words the full capacity of both generators is available for hoisting. With the hookup shown in Fig. 14, it is necessary to use generators of almost identical rating because they are run in series, and if different ratings are used for the two generators then the hoisting power available is limited to twice the rating of the small generator.

The facts that the initial cost of complete electric rigs is rather high, and that the driller is more familiar with mechanical rigs than with electrical rigs, because of the larger number of mechanical rigs in service, led to the development of the arrangement shown in Fig. 15. This arrangement is almost identical with that shown in Fig. 2 with the exception that a generator is used instead of the reverse clutch, and the conventional draw-works motor drive is used. This arrangement gives the high-torque, low-speed characteristics of the direct-current system for hoisting, allows a wide range of table speeds, and at the same time allows the pump to be operated at its best operating point. In this scheme the generator and exciter are designed for a wide speed variation in some cases as high as 50 per cent. The engines are normally operated with compounding drives in service, which means they are not only compounded during the hoisting operation but also for normal

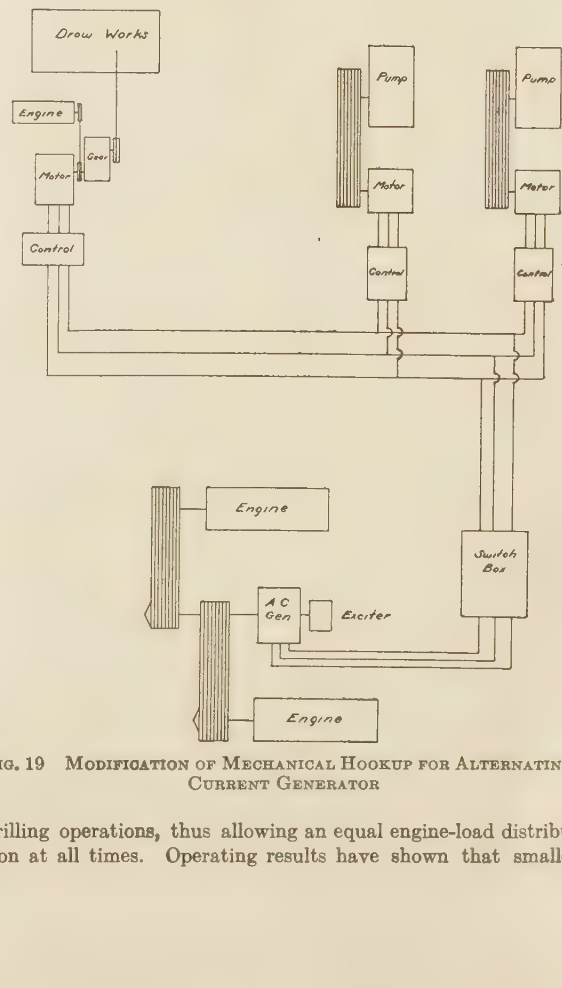

FIG. 19 MODIFICATION OF MECHANICAL HOOKUP FOR ALTERNATING-CURRENT GENERATOR

drilling operations, thus allowing an equal engine-load distribution at all times. Operating results have shown that smaller

engines can be used with this design than for any of the straight mechanical rigs for the same duty.

The fact that a large number of alternating-current rigs in the Seminole and Oklahoma City fields were operated on purchased power and were subsequently stacked, led to some thought being given to alternating-current generator plants driven by internal-combustion engines, thus allowing these rigs to be salvaged and put back in service. Several different designs have been made to accomplish this purpose. One such design is shown in Fig. 16. This design includes three slow-speed, twin-cylinder oil engines all belted to a common line shaft which in turn is direct-connected to an alternating-current generator. From that point on conventional electrical connections were used.

Because of the inherent torque characteristics of the alternating-current motor and also the fact that it is impossible to differentially wind alternating-current generators and provide nonstalling features for the engine, it has been necessary to provide greater engine horsepower than with the direct-current units to accomplish the same results. This is shown graphically in Fig. 17, which shows the torque available with both types of equipment, and in Fig. 18 which shows the useful horsepower available for both types. In Fig. 19 is depicted a modification of the mechanical hookup for alternating-current generators.

In all the alternating-current designs it will be noted that one generator is used with one or more engines to drive it. An attempt was made several years ago to use the conventional method of paralleling alternating-current generators electrically. Because of the instability of the ordinary governors for internal-combustion engines, it was not possible to keep the generators in parallel with any degree of satisfaction.

The authors have attempted to show, without thought being given to the advantages and disadvantages of the different arrangements described, the several methods of mechanical or electrical transmission now in common use for the utilization of the power of the internal-combustion engine in rotary drilling operations. Like all other industries, it would be almost safe to say that the initial cost of the equipment is represented in some advantages or disadvantages. For instance a straight mechanical rig is the cheapest but the first cost introduces some very decided limitations. The half-electrical and half-mechanical rig has eliminated some of the limitations of the straight mechanical rig but is more costly, while the full direct-current electrical rig is the costliest; but it equals if not excels the results from the steam rotary drilling rig with great savings in fuel and water.

The Collection and Evaluation of Data for the Design of Steam-Generating Units

By B. J. CROSS,[1] NEW YORK, N. Y.

The author points out that rational progress in the development of steam-generating units can be made by careful deductions from known facts about such units, and by extrapolation of actual operating data. The purpose of the paper is to relate some of the difficulties encountered, and the care necessary, in making field measurements in obtaining such operating data.

THE PERFORMANCE of a steam-generating unit is "built" into it by the design. Its performance is fixed by the arrangement of heating surfaces and the path of gases over these surfaces. If the surface could be maintained clean and the gas flow uniformly distributed over it, its performance could be accurately predicted. Uncertainties of performance are the result of fouling of the surfaces and unequal distribution of gases.

Rational progress in the development of steam-generating units must be made step by step, the operating experience of one design leading to the development of the next. It is obvious, however, that if there is to be progress, ventures must be made into new territory. The hazards of failure of such ventures can be greatly reduced by careful deduction from known facts and extrapolation of actual operating data. The purpose of this paper is to indicate some of the difficulties encountered and the care necessary in making field measurements in obtaining such operating data. For the determination of overall performance of a steam-gênerating unit, only end-point data are necessary. Heat input, heat output, and heat lossses only need be considered. For the purpose of obtaining design data, measurements throughout the unit are required and the performance of each part of the unit must be carefully studied.

The rate of heat transfer from a hot fluid to cooler absorbing surfaces may be calculated with a satisfactory degree of accuracy when the mass and temperature of the fluid are known, when the flow of fluid is uniformly distributed over the heating surfaces, and when the heating surfaces are clean. These ideal conditions never occur in practice, and the designer of heat-absorbing equipment must consider both theoretical and practical data; in general, the shape or slope of an absorption curve may be determined from a theoretical consideration, but empirical constants must be established to locate the curve with respect to its reference axes.

The problem of design of a steam-generating unit begins with the furnace. It is there that the heat latent in the fuel must be developed for delivery to the boiler. In the not far distant past, the sole function of the furnace was considered to be the evolution of heat and any absorption of heat that occurred was merely incidental to the exposure of boiler tubes to the furnace. Water-cooled surface was first introduced into the furnace to protect refractories from erosion by molten ash. It next replaced refractory surface and in the high-capacity furnace of today, refractory surfaces are almost completely eliminated and the absorption of heat has become an important function. In units of recent design 40 to 50 per cent of the available heat in the fuel is absorbed in the furnace.

From a consideration of combustion only, the rating or duty of a furnace is expressed by the heat liberated per cubic foot of combustion space and the effectiveness of the furnace is measured by the composition of gases delivered to the boiler. Considered as a heat-absorbing unit, the rating of a furnace is the heat liberated per square foot of radiant-heat-absorbing surface, and the measure of its performance is the temperature as well as the composition of the gases leaving the furnace.

The area of radiant-heat-absorbing surface may be calculated in various ways. It may be based on the entire circumference of furnace tubes, on one half the circumference, on projected surface of the tubes only, or on the projected surface of tubes and appurtenances such as fins, pegs, or attached blocks. As long as absorption rates are determined on the same basis, it does not matter how the radiant heating surface is computed. Projected areas are recommended for simplicity of calculation. A large part of the discrepancy in published values for furnace absorption rates is due to differences in methods of computing radiant heating surface. Convection-heat-absorbing surface is fixed by official definition. Radiant-heat-absorbing surface should also be officially defined.

The transfer of heat in the furnace is principally by radiation and takes place according to the Stephan-Boltzmann law, involving the difference in the fourth power of the absolute temperatures of the radiating surfaces. As applied to heat absorption in a furnace, the equation of this law may be written

$$Q = C_1A_1T_1^4 - C_2A_2T_2^4$$

where Q is the quantity of heat absorbed, C is the radiation constant including the emissivity factor, A is the surface area, and T is the absolute surface temperature. The subscripts 1 and 2 refer respectively to the hotter and the cooler surfaces. This expression treats each surface separately as radiating surface and assumes the difference in heat radiated to be the net heat transferred.

The factor C_1 can be based on an emissivity factor of unity without serious error. The area A_1 will vary with the method of firing and also with the rate of firing and percentage of excess air. If we consider the outer envelop of the flame as the active radiat-

[1] Assistant Engineer, Development and Research, Combustion Engineering Company, Inc. Mem. A.S.M.E. Mr. Cross was graduated from Colorado College in 1913 with an A.B. degree. He was then employed by the Blue Bird Gold Mining Company, Cripple Creek, Colo., in drafting, surveying, and sampling. In 1914 and 1915 he served with the T. M. Park Mining Company, Tucson, Ariz. He taught physics and chemistry in the high school at Glenwood Springs, Colo., from 1915 to 1917. From 1918 to 1920 he served with the U. S. Bureau of Mines at Pittsburgh, Pa., and Seattle, Wash. From 1920 to 1931 he was engaged in research and testing for the Combustion Engineering Company, Inc., New York, N. Y. He entered the employ of FosterWheeler Company in 1931 as research and design engineer, and resigned in 1934 to assume his present position.

Contributed jointly by the Heat Transfer Committee of the Process Industries Division and the Power Division and presented at the Annual Meeting of The American Society of Mechanical Engineers, held in New York, N. Y., November 30 to December 4, 1936.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until April 10, 1937, for publication at a later date. Discussion received after the closing date will be returned.

ing surface, the area A_1 will always be smaller than A_2 which is its limiting value. The temperature T_1 does not exist as such. It is the average temperature corresponding to the average rate of absorption. The factor C_2 for the wall surface depends upon the type of wall construction and upon its state of cleanliness. The area A_2 is fixed by the design. The temperature T_2 of the

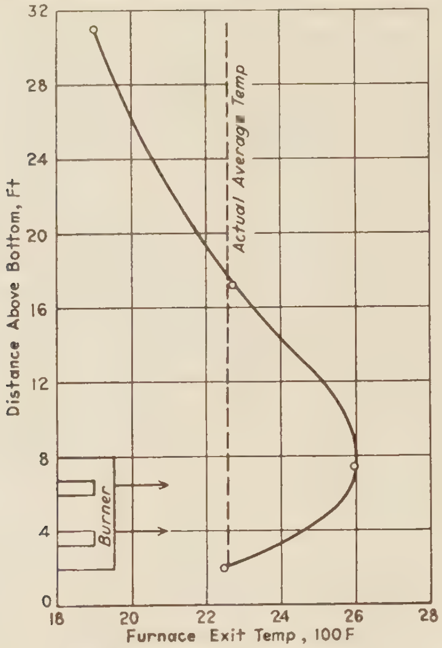

Fig. 1 Furnace-Temperature Gradient for a Completely Water-Cooled Furnace Fired With Powdered Coal

wall surface is controlled in some measure by the design pressure but is greatly affected by the state of cleanliness. For a clean tube surface the temperature T_2 cannot greatly exceed the temperature corresponding to the operating steam pressure, but if covered with ash it can assume any temperature up to the fluid temperature of the slag. When boilers are operated at constant high ratings, wall tubes may become encased with a thin layer of almost vitreous slag which must be close to the molten temperature on the outer surfaces. When the rating is lowered, these accumulations fall off. When the boiler is operated with variable rating, slag is constantly building up and falling off so that furnace surfaces remain comparatively clean.

A furnace-temperature gradient is shown in Fig. 1 for a completely water-cooled furnace fired with powdered coal. The burners are arranged tangentially at the bottom of the furnace. The temperatures shown were measured with thermocouples of platinum platinum rhodium inserted through openings at different levels in the furnace. They are average readings over an insertion distance of about 8 ft. At the lower part of the furnace they may be correct within 100 F. The theoretical flame temperature was 3600 F, while the maximum measured temperature was 2600 F. The theoretical temperature of flame cannot be attained unless the combustion of the fuel is instantaneous. Actually, a definite time is required for combustion, and radiation occurs during combustion so that the theoretical temperature is never reached.

The only furnace temperature that can be measured with any degree of accuracy is the temperature of gases leaving the furnace, and most of the methods that have been proposed for computing furnace absorption rates are based on the Stephan-Boltzmann law using the furnace-outlet temperatures.

Firing rates and absorption rates are plotted in Figs. 2 and 3 against furnace-outlet temperatures. Fig. 2 shows curves for a completely water-cooled furnace, tangentially fired with pulverized coal. This is the unit, the furnace temperature of which is shown in Fig. 1. Fig. 3 shows a curve for a vertically fired unit also completely water cooled. For the purpose of comparison,

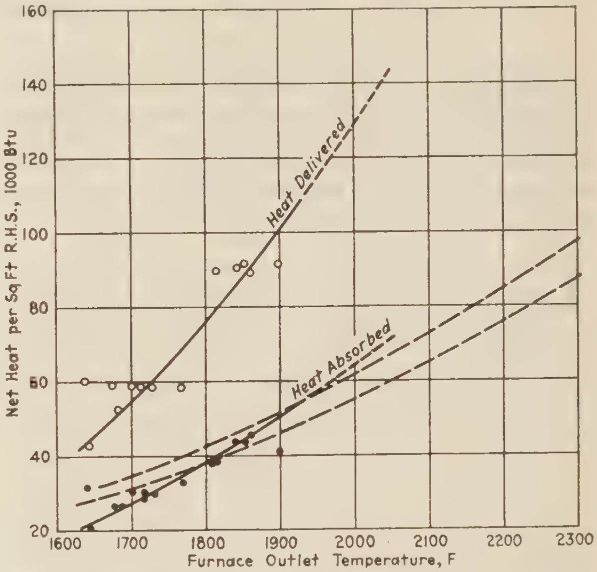

Fig. 2 Firing and Absorption Rates in a Water-Cooled Furnace Fired With Powdered Coal

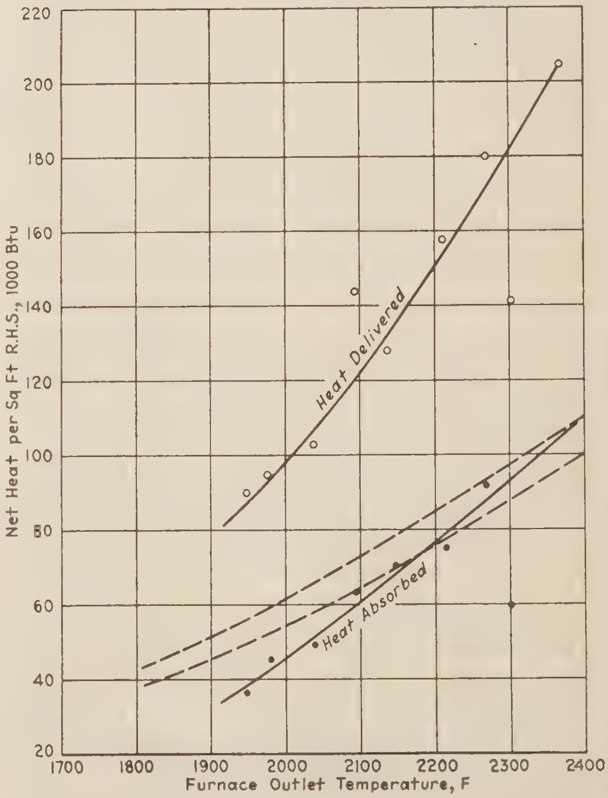

Fig. 3 Firing and Absorption Rates in a Water-Cooled Vertically Fired Furnace

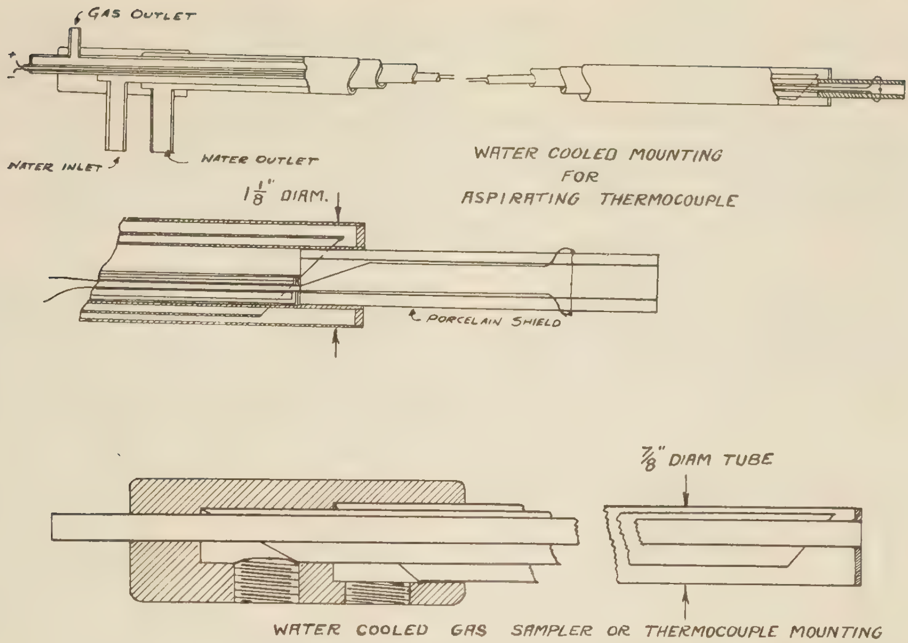

Fig. 4 Plain and Velocity Thermocouples in Water-Cooled Mountings

the Stephan-Boltzmann curve, based on furnace-outlet temperatures, is shown in each figure. The heat rates shown on the ordinates is the net heat per square foot of radiant heating surface. This net heat is equal to the gross heating value of the fuel plus the heat in the preheated air less the latent heat of water vapor and the heat in unburned carbon. It will be noted in both of these figures that the actual absorption rate has a steeper slope than the Stephan-Boltzmann curve. This may be accounted for by the increasing value of A_1 with higher combustion rates and also by an increase in the convection component with the increased velocity of gases in the furnace. These figures indicate the difficulties in applying the Stephan-Boltzmann law to the solution of problems in furnace heat transmission. That these difficulties may not be insurmountable is indicated by some of the recent treatises on the subject.

The measurement of the temperature of a stream of gases adjacent to or surrounded by cooler surfaces is liable to a "radiation error." Theoretically, with any instrument having a mass exposed to the gases, the true temperature will never be indicated. The instrument is receiving heat by conduction and radiation from the gases and is losing heat by radiation to the cooler surfaces. It will finally assume an equilibrium temperature somewhat different from that of the gases. The smaller the mass of the instrument, the closer will be the equilibrium temperature to the true gas temperature. Because of the small mass possible, the thermocouple is well adapted to the measurement of gas temperatures. For the furnace-outlet temperature thermocouples of platinum platinum alloy are necessary, preferably in water-cooled mountings. With such couples, wire diameters as low as 0.005 in. may be used. The use of small wire reduces the radiation error and also the error due to conduction of heat along the wire to the water-cooled mounting.

One difficulty that is experienced with thermocouples is that due to slag building up on the wire and increasing the effective diameter, a false reading results because of the shielding effect and increased radiation. The couple must be frequently removed and cleaned. Couples of the velocity type are sometimes used. Such couples have a refractory shield surrounding the hot junction to reduce the radiation and are also arranged so that gas may be drawn over the junction at relatively high velocity. Such couples give good temperature readings while they remain clean but they foul rapidly and require frequent cleaning. This is particularly true in powdered-coal furnaces.

Since a thermocouple located at the furnace outlet is exposed to radiation from the hotter furnace below it as well as to the cooler surfaces above, it is questionable whether the radiation error will be plus or minus. In several cases where the temperature was measured with two couples of 0.025 and 0.012 in. diameter, the larger couple gave the higher reading although the differences were not great. After experience with both shielded and bare couples, the author's preference is the bare couple. It is much easier to clean and does not require cleaning as often as the velocity couple.

Fig. 4 shows plain and velocity couples in water-cooled mountings. For maximum water area and minimum exposed surface, such mountings should be made up with thin-wall brass tubing. Lengths up to 12 ft can be handled without difficulty.

As the gas-temperature measurements at the furnace outlet are at the largest flow section of the unit, a large number of points must be taken to get an average, and considerable time is required for a traverse. Fortunately, while most large steam-generating units can be operated under quite steady conditions for periods of time long enough to make complete measurements over the entire unit, care should be taken that a change of operating conditions does not occur while the traverses are being made.

Ordinarily, the arithmetical average of the individual points of a temperature traverse of the furnace outlet may be considered to be a true average temperature. If there are wide differences in individual readings, differences in gas velocity may be suspected. If, however, the temperature be reasonably constant over the section, differences in gas velocity need not be considered.

The heat transfer for all surfaces above the furnace is chiefly by convection, radiation transfer becoming less and less a factor as the temperature of the gas is reduced. The factors controlling the convection-transfer rate have been the subject of much study and theoretical values can be calculated that have good agree-

ment with practical values. Heat transfer by convection is represented by the equation

$$Q = RS(tm)$$

where R is the convection-transfer rate, Btu per sq ft hr deg F; S is the surface, sq ft, and tm is the mean temperature difference between the gases and the surface. The heat transferred by convection also must equal the product of the weight, the specific heat and the temperature drop of the gases or

$$Q = Wc_p(t_1 - t_2) \text{ and } R = \frac{Wc_p(t_1 - t_2)}{S(tm)}$$

For the experimental determination of R, the temperature and weight of gas is required. An inspection of the last equation

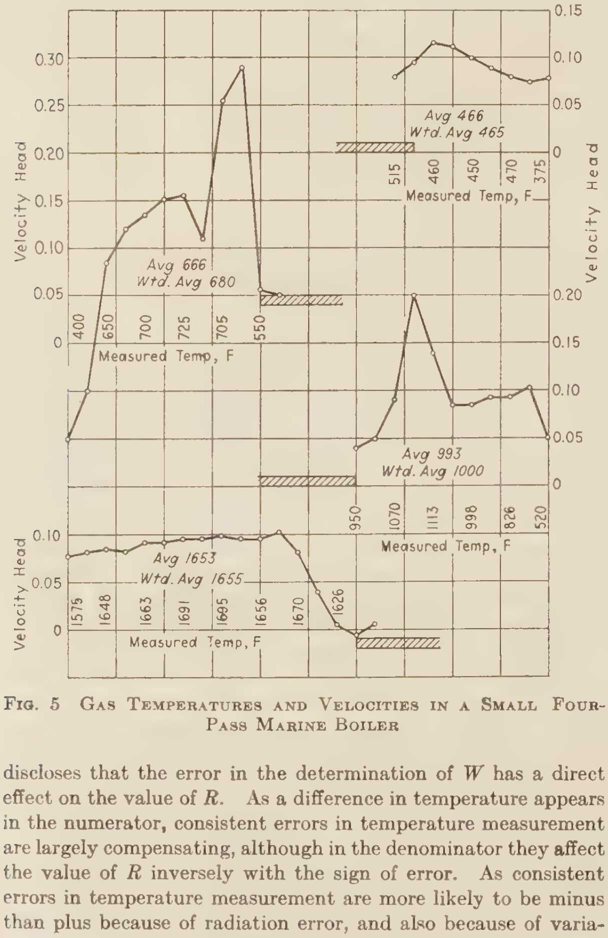

Fig. 5 Gas Temperatures and Velocities in a Small Four-Pass Marine Boiler

discloses that the error in the determination of W has a direct effect on the value of R. As a difference in temperature appears in the numerator, consistent errors in temperature measurement are largely compensating, although in the denominator they affect the value of R inversely with the sign of error. As consistent errors in temperature measurement are more likely to be minus than plus because of radiation error, and also because of variation in gas velocity, the determined values for R are likely to be high.

Unlike measurements at the furnace outlet, the radiation error in gas-temperature measurements in the boiler passes must always be negative, because the instrument used is completely surrounded by surfaces at a lower temperature than that of the gases. The radiation error is less at high boiler ratings when the gas velocity is high. Shielded velocity thermocouples or thermocouples made with small wire and small hot junctions should be used. The small-wire bare thermocouple is recommended for its simplicity. At the ratings at which present-day units are usually operated, the radiation error should not be large.

The effect of varying velocity when the arithmetical average of a number of readings is taken is to cause a minus error in the temperature. The transfer rate R varies with a power of the mass flow. If this exponent were unity, the transfer rate would increase at the same rate as the flow and the temperature of gas leaving a boiler would remain constant regardless of rating. Actually, the exponent is somewhat less than unity and the gas temperature increases with flow. The points of high velocity therefore become points of high temperature, and if given equal weight as in an arithmetical average, the average gas temperature would be in error on the low side.

Bulletin 214 of the U. S. Bureau of Mines describes tests on a small marine boiler during which tests special investigations of gas temperature and gas velocity were made. The results of one test on a four-pass boiler are shown graphically in Fig. 5 for each of the four passes. The arithmetical mean temperature is compared with a weighted mean based on velocity and density. It will be seen that in the first pass, where there is no relation between velocity and temperature, there is practically no difference between the arithmetical and weighted means. In the second and third passes, after the gases have passed over the heating surface, the high-velocity points become high-temperature points and the weighted average gives a higher value than the arithmetical average. The difference in the two averages is, however, surprisingly small considering the range in velocities. In the fourth pass there is less variation in velocity and temperature and the arithmetical and weighted mean temperatures are practically the same.

In most instances the arithmetical average of a number of readings taken over a section of gas flow will be sufficiently accurate. When a high degree of accuracy is required or when great differences in velocity occur, velocity-head and temperature readings should be taken simultaneously and the weighted average obtained. The design of a combination thermocouple and pitot tube is not difficult, particularly as only relative and not absolute velocities are required.

The weight of gas resulting from the combustion of fuel may be determined by means of a carbon balance. The weight of dry gas per pound of fuel is given by the familiar formula

$$W \text{ (dry)} = \frac{4CO_2 + O_2 + 700}{3(CO_2 + CO)} C_b$$

where the various gases are in per cent by volume and C_b is the pounds of carbon burned per pound of fuel. To obtain the total weight of gas per pound of fuel there must be added to the dry gas the moisture in the fuel, the water vapor formed from burning hydrogen, and the water vapor in the air used for combustion.

To obtain a representative value for the composition of gas at a flow section of the boiler, samples must be at a number of points corresponding to the points of temperature measurement.

Except for the fact that air infiltration occurs throughout the unit, only one determination of gas flow would need to be made for studies of the entire unit. Air infiltration increases with draft and is, therefore, likely to be higher in the latter stages of heat absorption; that is, in the economizer and air heater. For a complete study of the steam-generating unit, four gas-sample traverses are necessary: One at the furnace outlet in connection with studies of the furnace, superheater, and boiler surface below the superheater; one at the boiler outlet; one at the economizer outlet; and one at the air-heater outlet. For each of these sections of heating surface beyond the first pass, the average of the inlet- and outlet-gas weights should be used. As in making temperature averages, differences in gas velocity must be considered in making up the average of the analysis of gas samples, and if great differences in gas velocity are found to exist, weighted averages should be used.

The rate of heat transfer in that portion of boiler surface below the superheater is of interest chiefly in the superheater design. The temperature of the gases leaving the furnace must be reduced to accord with the degree of superheat required and also to comply with the limit set by the temperature tolerance of the metal of the superheater elements. With the present-day demand for higher superheat temperature, and with the development and use of high-temperature alloys, the amount of surface below the superheater is becoming smaller and wider tube spacing is being used. This smaller surface with wider tube spacing presents new factors in the mathematical determination of heat-transfer rates which are perhaps not covered in existing formulas, and new experimental data are required.

The superheater may be either of the convection or radiant type or a combination of both types. Radiant superheaters are located in the furnace and may be treated in a similar way to water-cooled surface. Convection superheaters are located in the path of gases after a part or all of the boiler surface. The calculation of the heat-transfer rate for a superheater is more involved than for water-evaporating surfaces, largely because the mean temperature difference is difficult to determine. The multiloop design of large superheaters does not permit either a true counterflow or true parallel-flow arrangement. For this reason, superheater transfer formulas are almost entirely based on empirical data.

Economizers, while designed on a counterflow principle are not, strictly speaking, true counterflow, but similar to the superheater are partially crossflow. However, because of the comparatively high heat capacity of water, there is only a small water-temperature rise over the length of a single tube and for practical purposes, economizers of the usual design may be considered truly counterflow.

Gas temperatures and gas weights for the economizer may be determined as heretofore described without much difficulty. The sections of gas flow are smaller than for boiler passes and the traverses are correspondingly simplified. The heat absorbed by an economizer may be determined both by the gas-temperature drop and by the water-temperature rise, one method serving as a check upon the other. The latter method probably is the more accurate as water temperatures may be measured more accurately than gas temperatures.

The transfer of heat in the economizer more than for any other part of a steam-generating unit, lends itself to mathematical analysis. When the economizer elements have extended surfaces, the effectiveness of such additional surfaces must be determined experimentally. A factor may then be applied to the total surface to reduce it to effective tube surface.

Air heaters are of three general types: The plate or envelope type, the tubular type, and the regenerative type. The plate and tubular heaters are similar in principle differing chiefly in the method of confining and separating the air and gas. In the regenerative air heater, the heat of the gas is first imparted to a solid. This solid is then transferred mechanically to the air stream and the heat is given up to the air. The principle of heat transfer is not greatly different from the other types of heater, but the temperature gradients are somewhat involved and difficult to define. An exact mathematical analysis and derivation of air-heater transfer rates is impractical and design formulas are based largely on empirical data.

Air heaters are always designed on the counterflow principle, but because of entrance and exit requirements, a part of the path is crossflow. The longer the heater can be made, the more nearly it approaches true counterflow. In all air heaters, the transfer of heat involves two gaseous mediums and the overall transfer rate from the gas to the air is a combination rate based on the transfer rate of the gas to a solid and from the solid to air. If R_g is the gas transfer rate and R_a is the air transfer rate, the net rate of transfer R from the gas to the air is expressed by

$$\frac{1}{R} = \frac{1}{R_g} + \frac{1}{R_a}$$

While this principle holds true for all transfer rates throughout the boiler, the transfer rate on the water sides of tubes is so high and the value of its reciprocal is so low that it may be neglected.

The heat absorbed by an air heater is determined by the weight and temperature drop of gas passed through it. If the weight of air passing through the heater could be accurately determined, it would serve as an independent check on the heat absorbed. Because of air infiltration ahead of the air heater, the weight of air passing through the heater is always less than the

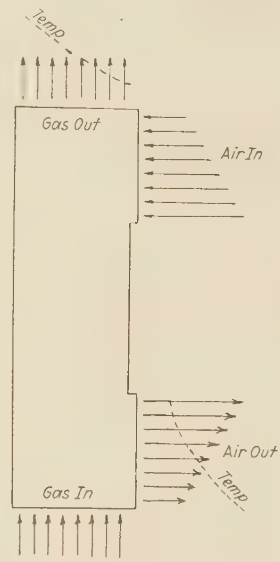

Fig. 6 Diagram of Air Heater Illustrating Unfavorable Flow Conditions

amount indicated by the analysis of gases passing through the heater.

The temperature of gases to and from the heater and the temperature of air from the heater may be determined by temperature traverses at sections of flow. Because the encasing walls of ducts and flues absorb but little heat, their temperature is not greatly below that of the gases and there will be no appreciable error due to radiation. However, differences in velocity must be considered. Points of high gas velocity become high-temperature points as has been previously described. However, points of high or low gas temperature occur independently of gas velocity because of differences in air velocity. On the air side of the heater, high-velocity points become low-temperature points and high- and low-temperature points may also occur independently of air velocity, being caused by differences in gas velocity. Ordinarily, air heaters are designed in such a way that large differences in velocity of either gas or air cannot occur, but sometimes the design is affected by mechanical interferences and space limitations and unfavorable conditions for gas and air flow may result. An extreme case is illustrated in Fig. 6. The velocity variation is indicated by the length of the arrows, and the variation in temperature is indicated by the curves. In such a case weighted averages would be necessary to obtain representative temperatures.

The design of steam-generating units will probably never ap-

proach anything like an exact science. The behavior of water in its liquid and vapor forms has been thoroughly investigated and accurate tables of its properties have been prepared. Because of its high heat capacity and high density, it is ideal as a carrier of energy. It can be confined to small tubes and its flow directed, if not with accuracy at least with certainty. As an absorber of heat it leaves little to be desired.

On the other hand, fuels are many and varied. They may be solid, liquid, or gaseous. They vary widely in physical properties and chemical composition and contain many impurities. They must be burned with air which contains 80 per cent inert substance. The hot gases derived from their combustion have low heat capacity and low mass. Because of the energy cost in moving so tenuous a medium, velocities are limited and large flow sections must be provided. These gases must be passed in series over each of the several parts of the steam-generating unit. Thus, the performance of each part is affected by the performance of all preceding parts.

Considering the difficulties involved, the actual performance of steam-generating units in general compares favorably with design performance. That occasional departures occur indicates that all factors are not completely under control. Emphasis should be made, not on occasional misses but on the large number of hits.

Determination of the Effect of Certain Installation Conditions on the Coefficients of Sharp-Edged Orifices

By S. R. BEITLER[1] and J. E. OVERBECK,[2] COLUMBUS, OHIO

This paper presents the results of a study made to determine the effects of certain installations on the coefficients of discharge of sharp-edged orifices. The coefficient determinations were made with the orifice plates clamped between flanges made up on the end of pipe so that no appreciable gap existed between the end of the pipe and the orifice plate. Some of the orifice flanges were constructed with a core or recess which left a gap of an inch or more between the end of the pipe and the orifice plate, this being done to simulate meters of this type now used to a greater or less extent. The authors present results obtained from the tests of such orifices set in 2-, 4-, and 8-in. pipes, as well as results from tests of standard-reference orifices. All results are presented graphically.

THE MAJOR part of the research work of the Joint Committee of The American Society of Mechanical Engineers and the American Gas Association on Orifice Coefficients was the determination of the correct coefficients of discharge of sharp-edged orifices. The installation of the orifice has considerable influence on the value of the coefficient, and therefore the committee was forced to make a comprehensive study of the effects that various conditions of installation had on the coefficients of the orifices. The coefficient determinations were made with the orifice plates clamped between flanges made up on the end of pipe so that there was no appreciable gap between the end of the pipe and the orifice plate. The pressure-tap holes were 0.25 in. in diameter.

In some commercial installations, especially for the measurement of natural gas, the orifice flanges were constructed with a "core" or recess which left a gap of an inch or more between the end of the pipe and the orifice plate. This type of flange was used generally only with meters having flange and pipe taps. The diameter of this core, or recess, was usually about the same as the outside diameter of the pipe. Most of these orifice flanges, as well as some of the newer ones without recesses, were constructed with large pressure-tap holes in order to reduce the possibility of the connections being clogged by dirt or ice.

Since the users of meters having this type of flange would be placed at considerable expense to reconstruct all meter flanges that were recessed, and since operating difficulties might ensue with the use of too small pressure taps, the committee felt that an investigation should be made to determine the effect of these types of installations on the coefficients of orifices. These tests were conducted at the South Columbus Metering Station of the Ohio Fuel Gas Company during the fall and winter of 1932–1933.

The method of conducting the tests was to compare two similar orifices in different settings in series, measuring the same gas. Pipes of 2, 4, and 8 in. diameter were used, and comparisons were made using both flange and pipe taps. Two sets of orifices were used for each pipe size. For the 2-in. line there was a total of ten orifices with respective diameters of $^1/_2$, $^3/_4$, 1, $1^1/_4$, and $1^1/_2$ in. The diameters of the orifices for the 4-in. line were $^1/_2$, 1, $1^1/_2$, $2^3/_8$, and 3 in., while those in the 8-in. line were 1, 2, 3, $4^3/_4$, $5^3/_8$, and 6 in. There were 12 orifice plates for the 8-in. line and ten for the 4-in. line.

The orifice plates were made of monel metal $^1/_8$ in. thick punched to the proper outside diameter with the orifice carefully bored to size and the edges scraped to give a sharp square edge. The edges were inspected carefully and were found to be as nearly perfect as was possible with commercial manufacture. The plates were made in the Columbus shops of the Ohio Fuel Gas Company.

Two types of orifice flanges were used for each size line. The one type used at all times for the standard or so-called reference flange, and at times in the second or commercial flange, was made with steel flanges carefully welded to the pipe so that the end of the pipe was flush with the face of the flange and the pipe was smooth and straight inside. This type was called a "steam-type flange." The other type, known as the recessed flange, was made in one of two ways. For the flange-tap tests, used orifice flanges were taken from the stock of the Ohio Fuel Gas Company and screwed onto the end of the pipe in the usual manner. When it was desired to find the effect of different lengths of core, the core was cleaned and an attempt made to use filler rings in the core. It was found that it was very difficult, if not impossible, to fit a ring so that it was smooth inside the pipe wall. Fig. 1 shows the 8-in. cored flange and filler ring.

In some cases different cored flanges were tried with different diameters and lengths of cores. At times different combinations of cored and steam-type flanges were used to determine whether the inlet or outlet core was affecting the coefficient.

For the flange-tap tests, the piping to the flanges was arranged

[1] Assistant Professor of Mechanical Engineering, Ohio State University. Mem. A.S.M.E. Mr. Beitler received the degree of bachelor of mechanical engineering at Ohio State in 1920. In 1920–1921 he served as apprentice engineer with the Whiting Corporation of Harvey, Ill. Since 1921 he has been at Ohio State University as assistant and instructor in mechanical engineering. From February, 1927, to date he has been consulting research engineer for the Bailey Meter Company, Cleveland, Ohio.

[2] Gas Measurement Engineer, The Ohio Fuel Gas Company. Mr. Overbeck has been engaged in gas-measurement activities since 1916, with experience in installation, operation, and maintenance of practically every class of gas meter. He has been associated with the research studies made by the Gas Measurement Committee of the American Gas Association and has taken an active part in the research work conducted by the joint A.G.A.-A.S.M.E. Orifice Coefficient Committee.

Contributed by the Joint Committee of The American Society of Mechanical Engineers and the American Gas Association on Orifice Coefficients and presented at the Annual Meeting of The American Society of Mechanical Engineers held in New York, N. Y., November 30 to December 4, 1936.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until April 10, 1937, for publication at a later date. Discussion received after the closing date will be returned.

as shown in Fig. 2. Although Fig. 2 shows the arrangement of the 4-in. line, the arrangement of the piping for the other two lines was similar. The gas used was supplied through valves from a high-pressure line and was dumped into the intermediate-pressure line supplying the city of Columbus after going through the test setup. Following the regulating valve, the line was straight for about 40 pipe diameters, at the end of which the reference flanges were mounted. They were preceded by

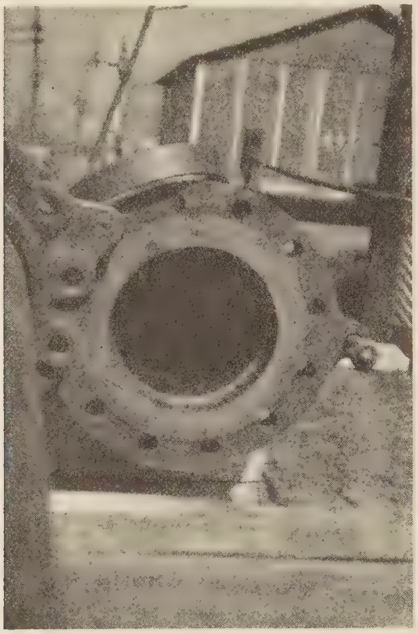

Fig. 1 The 8-In. Recessed Flange and Filler Ring

straightening vanes at six diameters on the inlet of the flange. The line then led to a header, and two lines connected this header to another similar header. These lines were valved so that the gas could be directed through either line. The commercial flanges were mounted in these lines, the steam-type flange in one and the recessed flange in the other. Both flanges were preceded by straightening vanes. The second header was then connected through proper valves to the intermediate-pressure line. This arrangement made it possible to change the orifice in the commercial flange from one type of flange to another without disturbing the orifice in the reference flange.

The general piping layout for the pipe-tap tests is shown in Fig. 3. Although Fig. 3 shows the piping arrangement for the 4-in. line, the arrangements for 2-in. and 8-in. lines were similar to it. The gas was drawn from the same high-pressure line and dumped into the same intermediate-pressure line. The same steam-type flange was used for the reference flange, and the commercial flange was mounted directly below it in the straight pipe. No manifold was used because of the much greater length of pipe required for the pipe taps. Instead of using runs of manifolded pipe for the commercial flanges, the runs were constructed so that they could be interchanged, thus making it possible to put either a steam-type or a recessed-type flange into the line. Fig. 4 shows the measuring station, and the 8-in. line for testing pipe taps.

The static and differential pressures across the orifices were measured by means of manometers mounted as shown in Fig. 5. The static pressure was measured by means of single-leg mercury manometers having a pressure range of about 80 in. Hg. For some of the runs using pipe taps, the pressure in the intermediate-pressure lines was so high and the flow was so great, that the pressure ran higher than could be measured with these manometers and it was necessary to put temporary extensions on the manometers.

The differential pressure was measured by ordinary 50-in. U-type water manometers. The manometers were set up inside a heated building—the one on the extreme left in Fig. 4—and the connections were made to the orifice flanges by means of $^3/_8$-in. pipe and short lengths of $^3/_8$-in. rubber tubing. Care was used in making all pipe joints to eliminate leaks.

Finned-type thermometer wells were placed in the line below each orifice. Mercury-in-glass thermometers were inserted in these to measure the temperature.

The method of taking data was as follows. Two plates with orifices of the same diameter were chosen and placed in the

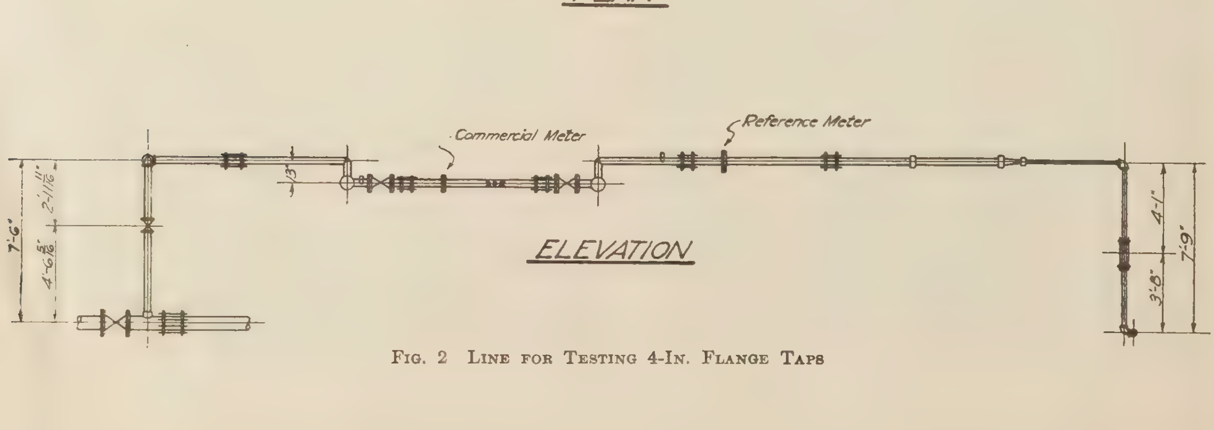

Fig. 2 Line for Testing 4-In. Flange Taps

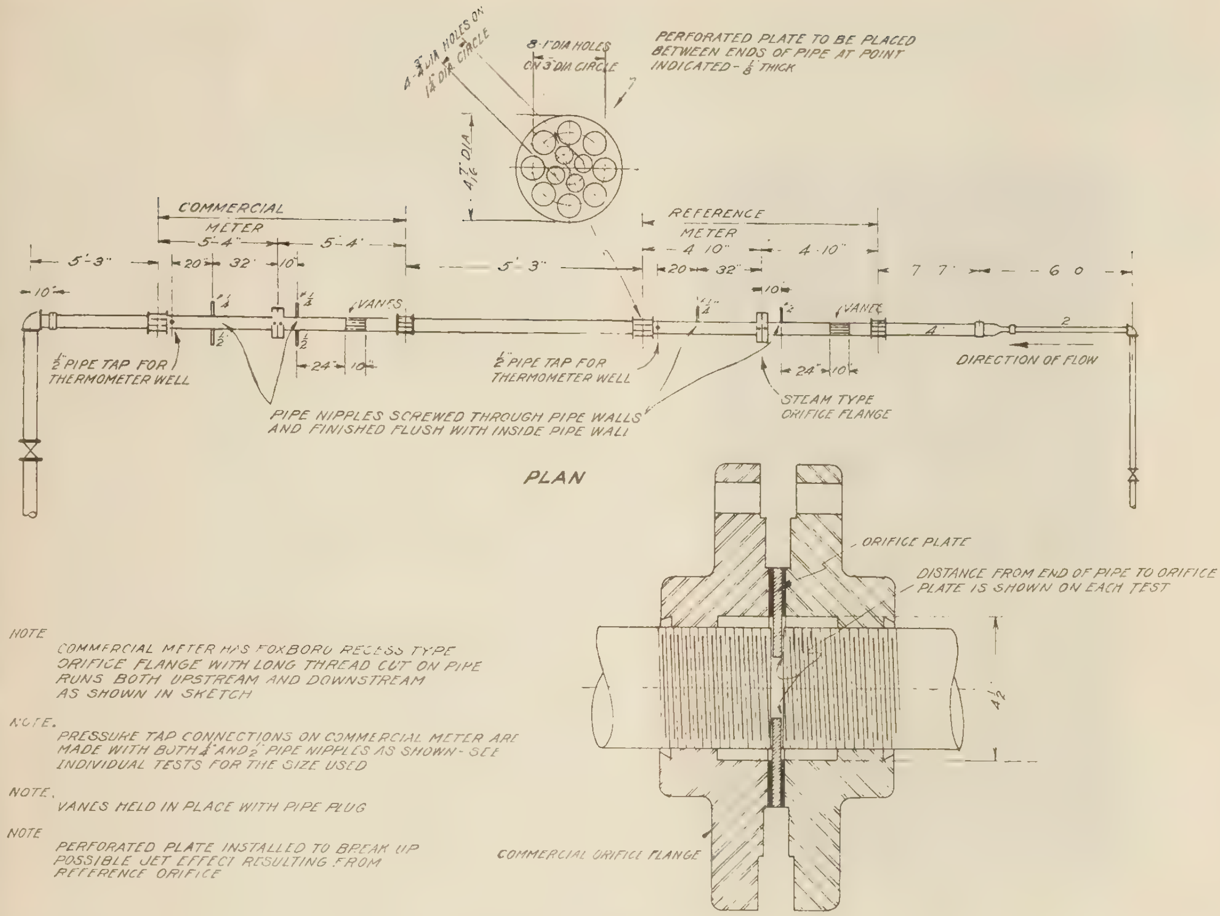

Fig. 3 Line for Testing 4-In. Pipe Taps

steam-type flanges, the one in the reference flange and the other in the commercial flange. The gas was then turned into the line and the flow adjusted until the differential pressure on the reference meter was approximately 10 in. of water. After conditions were steady, three readings were taken of the static and differential pressures and the temperatures for each orifice. The flow was then changed to give a pressure differential of about 25 in. of water and the readings repeated. This was repeated for pressure differentials of 50 in. and 80 in. of water. The plates were then reversed, that is, the plate which had been in the reference flange was placed in the commercial flange and the same series of tests run. The plate in the commercial steam flange was then transferred to the recessed flange and a series of tests run. The plates were again reversed and this series repeated. This general procedure was followed with all of the tests using various types of flanges and various sizes of pressure-tap holes in the commercial flanges.

Results

The results will be given only in graphical form. The general method of analysis was as follows:

The data taken for each test run was first averaged and the calculation was made to determine the ratio

$$r = \frac{K_C}{K_R} = \sqrt{\left(\frac{H_R P_R T_C}{H_C P_C T_R}\right)}$$

where H = differential head, in. water; P = absolute pressure, in. Hg; T = absolute temperature, F; $(\ )_R$ refers to the reference meter; and $(\ )_C$ refers to the commercial meter.

Fig. 4 Measuring Station and Line for Testing 8-In. Pipe Taps

This ratio r gives the value of the coefficient of discharge of the commercial plate divided by the coefficient of the reference plate, and indicates the effect on the coefficient of installation of the orifice. The results of the calculations for any one type of commercial flange were then plotted, the ratio r being plotted against the reference differential head. Since both plates were used in both flanges this gave eight points for each series. A curve was drawn through the average of these points. The use of the reversed plates eliminated any effect of orifice edge

and should have canceled out completely any difference in orifice construction. The effect shown was then the effect of the installation only. These curves for the 2-in. flange taps are shown in Fig. 6.

Next, the point on each curve at a differential pressure of 40 in. of water was plotted against diameter ratio of the orifice for each set of conditions. Fig. 7 shows these curves with the various arrangements of the commercial flange marked on each curve.

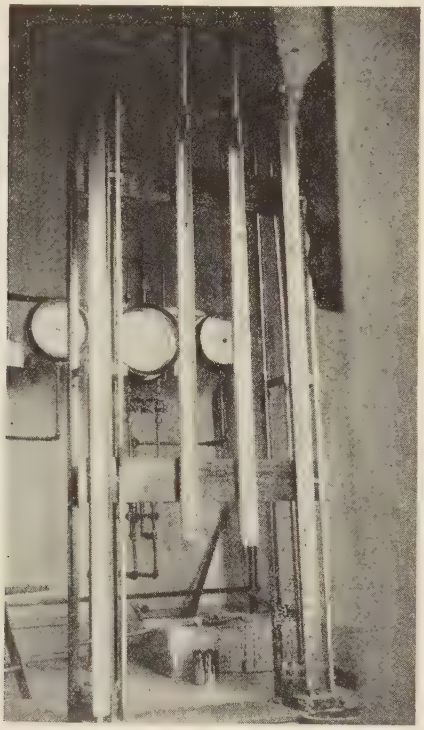

Fig. 5 Manometers Used in the Tests

Fig. 6 Head-Factor Curves for 2-In. Flange Taps

The curve for the steam flange with $^1/_4$-in. pressure taps was then assumed to be the curve without anything affecting the coefficient except uncontrollable items; values of the ratios read from this curve were divided into the ratio values for the other conditions to determine the effect on the coefficient of the various conditions under study. These were plotted and are shown in Fig. 8. The method used in obtaining results for the other lines was approximately the same.

Discussion of Results

The results will be studied for the different line sizes and the different pressure taps separately.

Effect on Flange Taps in a 2-In. Line. Reference to Fig. 8 shows that for these tests the use of $^{23}/_{32}$-in. pressure taps in place of $^1/_4$-in. taps had no effect on the coefficient of the orifice until a diameter ratio of 50 per cent was reached, and that for higher ratios the coefficient of the orifice was decreased slightly, the maximum effect being about 0.5 per cent at a diameter ratio of 75 per cent.

The effect of the recess is rather hard to understand. It will be seen that as the diameter ratio increases the coefficient of the orifice with the recessed flange is increased until there is a difference of about 1.75 per cent at a diameter ratio of 60 per cent, and then this effect decreases until at a diameter ratio of 75 per cent it has fallen to 0.75 per cent. The effect of the recess would undoubtedly be to increase the coefficient of the orifice since it would increase the turbulence directly ahead of the orifice and so decrease the contraction of the steam. Apparently, when the orifice ratio was large this effect was counteracted by some other effect, possibly friction, which decreased the effect of the core on the orifice coefficient. However, if the coefficients determined with steam flanges and $^1/_4$-in. pressure

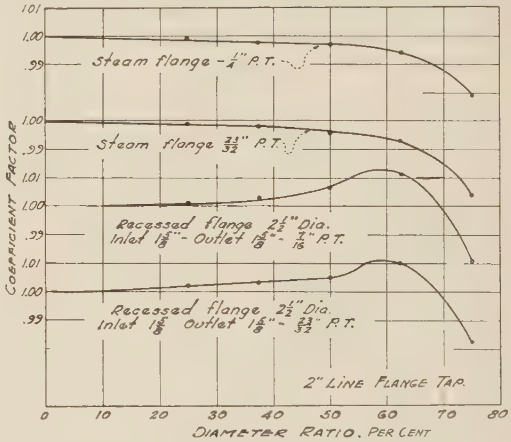

Fig. 7 Diameter-Ratio-Factor Curves for 2-In. Flange Taps

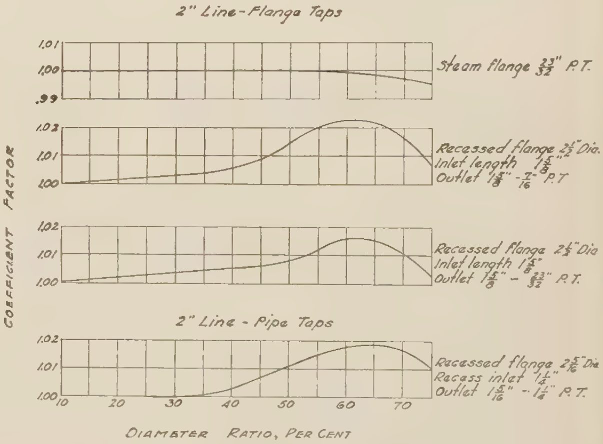

Fig. 8 Effect on Flange Taps and Pipe Taps in a 2-In. Line

taps are to be used with an accuracy of 0.5 per cent in this size line, it can be seen that the orifice diameter must be held below 35 per cent, and for high accuracy no cored flange should be used. It appears that for flange taps, the use of $^{23}/_{32}$-in. pressure taps has no effect on the coefficient of orifices with diameter ratios of less than 50 per cent, and the effect is only 0.5 per cent for an orifice with a diameter ratio of 75 per cent.

Effect on Pipe Taps in a 2-In. Line. For the pipe taps, the tests were only run on one cored flange. Graphical results of these tests are shown in Fig. 8. The shape of this curve is approximately the same as that for flange taps and recessed flanges, although the values are slightly different. However, the same conclusions as to the use of cored flanges with pipe taps can be drawn as were drawn for flange taps.

Effect on Flange Taps in a 4-In. Line. Fig. 9 shows the effect of flange taps installed in a 4-in. line, and also the results of some special tests which will be discussed later.

It will be seen from the first curve that the use of $^{23}/_{32}$-in. pressure taps in the place of $^{1}/_{4}$-in. taps had little effect on the coefficient of the orifices. The maximum difference was about 0.2 per cent for a diameter ratio of 80 per cent.

The use of the recessed flange caused an increase in the coefficient.

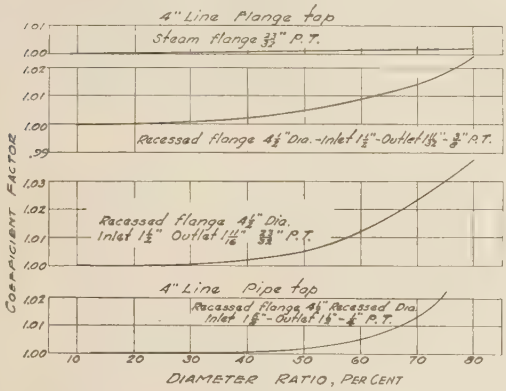

Fig. 9 Effect on Flange Taps and Pipe Taps in a 4-In. Line

cient. This increase started at a diameter ratio of about 30 per cent and amounted to about 0.5 per cent at a diameter ratio of 50 per cent, and rose to a maximum of about 2.4 per cent when the pressure-tap hole in the recessed flange was $^{3}/_{8}$ in. diameter. With $^{23}/_{32}$-in. pressure taps this maximum value rose to about 3.8 per cent.

It would appear that on this size line the use of the cored flange had two effects. The first was to increase the turbulence and so increase the orifice coefficient, and second, because of this turbulence, to build up the upstream pressure, which would also increase the coefficient. This would be more apparent when the larger pressure taps were used, since the larger taps would place the edge of the hole closer to the orifice.

It would appear from these tests that cored flanges should not be used in any case for orifices with a diameter ratio greater than 50 per cent, and for extreme accuracy the maximum usable ratio would be 30 per cent.

Effect on Pipe Taps in a 4-In. Line. Referring again to Fig. 9, the curve for pipe taps is similar in shape to that for flange taps but the deviation of coefficient does not start until a diameter ratio of 40 per cent is reached, and the maximum value is less than that for flange taps. The difference in coefficient is undoubtedly caused by the difference in flow through the orifice only, since the location of the taps precludes the possibility of the recess having any effect on pressure reading.

Effect of Length of Recess in a 4-In. Line. Fig. 10 shows the effect of changing the length of the recess. These curves, one for flange taps and the other for pipe taps, were obtained by varying the length of the recess, first on the inlet and then on the outlet of the orifice. While the one recess was being changed in length, the other side of the orifice was used with a steam-type flange. These curves show that the core on the outlet of the orifice had no effect on the coefficient for either flange or pipe taps. They also show that for the range tested, the length of the recess was the controlling factor of the effect on the coefficient, the longer the recess the greater being the effect. This was true for both flange and pipe taps, although the amount of the effect

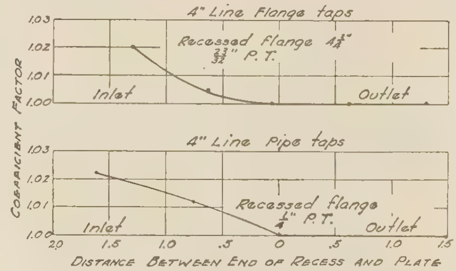

Fig. 10 Effect of Changing the Length of Recess in a 4-In. Line

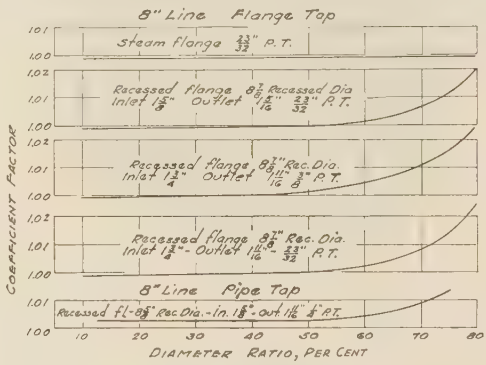

Fig. 11 Effect of Various Installations in an 8-In. Line

was greater for flange taps than it was for pipe taps. This was expected from the other tests since the flange-tap holes were $^{23}/_{32}$ in. diameter. It is also apparent from these curves that a $^{1}/_{4}$-in. gap between the orifice and flange has practically no effect, and this fact makes the construction of a satisfactory orifice flange simpler than it would be if it were necessary to have the end of the pipe flush with the face of the flange.

Effect on Flange Taps in an 8-In. Line. Fig. 11 shows the results of the tests on the 8-in. line. These curves are quite similar to those for the 4-in. line, and again are of the expected shape. It will be noted that apparently there was a difference of about 0.1 per cent between the $^{1}/_{4}$-in. and $^{23}/_{32}$-in. pressure taps, and that this difference carried through the whole set for the orifices with lower diameter ratios. This difference may well be experimental error, but since it was consistent for all tests, it was shown on the curves. The recess on this size line caused no appreciable error for orifice-diameter ratios of less than 50 per cent, and the effect was less than 0.5 per cent for a diameter ratio of 60 per cent, increasing to about 2.5 per cent for a diameter ratio of 80 per cent.

Effect on Pipe Taps in an 8-In. Line. The one apparent difference between the lower curve and the rest of the curves in Fig. 11, is the fact that there is a constant difference of about 0.3 per cent between the two coefficients at low ratio. This

is probably due to several things. First, because of seasonal conditions it was impossible to get extremely high flows through the plates and it was necessary to extrapolate some of the curves. Second, the steam flange for this line was made by putting filler rings in recessed flanges and it was difficult if not impossible to get the filler rings in the same at all times, so as to make a smooth approach. These facts probably account for this difference in all ratios and the shape of the curve represents the effect of the recess. If this is true there is no deviation of the coefficients until a diameter ratio of 55 per cent is reached, and the deviation is only about 0.5 per cent for a diameter ratio of 70 per cent.

Conclusion

The committee, in making its report, made the following recommendations concerning orifice flanges. It was recommended that the orifice pipe extend through the flange so that there is no recess greater than $^1/_4$ in. between the orifice plate and the end of the pipe, as measured parallel with the axis of the pipe. ...If in existing installations there is a recess preceding the orifice plate, either in the orifice flange or between the pipe and the plate, the length of which parallel to the axis of the pipe is greater than $^1/_4$ in., the orifice coefficients given in this report may be used only if the ratio of the orifice to pipe diameter does not exceed 0.3 for a 2-in. line, 0.4 for a 3-in. line and a 4-in. line, and 0.5 for all lines greater than 4 in.

Orifices installed according to the recommendations would then, from the curves shown, have a maximum error of coefficient of about 0.25 per cent if the maximum diameter ratio were used and less for smaller diameter ratios.

A study of all of the curves will show that the general shape of all is the same, but that there is considerable difference in the detail shape of the curves after the deviation in coefficient has started. This is probably due to the effect of different shapes and sizes of recesses, and shows that it is impossible to predict what correction to use if a diameter ratio higher than those given is used.

It is realized that this graphical method of study of the results may have some defects, but it was by far the simplest method available, and since the number of data available was very large, it appeared to be the only practical method. In actual comparison it could be shown that there was a variation of expansion factor between the two orifices in addition to the variation of coefficient and it might be thought that this would affect the results. This variation was there due to the fact that the pressure was always less at the commercial flange than it was at the reference flange. However, since the comparison was not made between the reference orifice and the recessed orifice directly, but between the orifices in a steam-type flange and in a cored flange, using the reference orifice as a base, the expansion factor should be so nearly the same for similar conditions that it would cancel out. With these facts in mind it is felt that the curves shown in this paper should accurately indicate the effect of the various conditions studied.

Cemented Carbide-Fitted Saws and Woodworking Knives

By C. M. Thompson,[1] Philadelphia, Pa.

The author reviews the development of the present design of carbide-fitted saws and gives some standard tooth angles required for various materials. Certain recommendations are made for the application of cemented carbides to woodworking knives and for the operation of carbide-fitted saws and knives on wood. Savings effected by the use of Carboloy saws are tabulated by the author.

In the early application of tungsten carbides to saws, it was natural that the inserted-tooth saw should appear first because of the comparative ease of brazing the carbide tip to the steel insert which in turn could be inserted in a hardened and tempered blade.[2] Such a saw is shown in Fig. 1. It soon became apparent, however, that tooth spacing closer than that possible with the inserted-tooth saw was necessary, particularly for smooth cutting and the sawing of thin bakelite and other abrasive materials which rapidly dull the steel saw. After several years of experimental work saws have been produced successfully in which the carbide tips are brazed directly to the steel blade, and in which the minimum tooth spacing is approximately $^5/_{16}$ in. These saws are now manufactured in diameters up to and including 16 in. Where larger diameters are required it is necessary to revert to the inserted-tooth saw. The solid-tooth carbide-fitted saw is shown in Fig. 2.

The widespread use of carbide-fitted saws has been somewhat curtailed by the cost and time required for sharpening. There are, in general, three forms of teeth required to meet the successful sawing of a great variety of materials on the market today. These tooth forms may be classified as (1) straight front, (2) alternate bevel, and (3) square and advanced.

These forms are shown in Figs. 3 to 7, inclusive. It can be seen that the alternate-bevel and square-and-advanced forms offer more difficult sharpening problems than the straight-front form. While the square-and-advanced form is primarily a metal-cutting design, the alternate-bevel form is necessary for sawing materials of a fibrous nature where a shear cut is essential for smoothness. The straight-front form is designed for sawing bakelite, hard woods, and other dense materials.

When it is considered that teeth with the alternate-bevel form are manufactured with extreme rake or undercut angles of 20 deg, alternately beveled faces of 30 deg, and alternately beveled tops of 25 deg, the acuteness of the points of the teeth becomes apparent. Former sharpening practice required the grinding of the carbide teeth followed by diamond lapping, which was a slow and costly procedure. Fortunately, the introduction of bakelite wheels impregnated with diamonds, which are now available in standard sizes and shapes, has materially decreased the sharpening time. These wheels not only cut faster than the grinding wheels but at the same time produce a cutting edge almost the equal of the diamond-lapped edge.

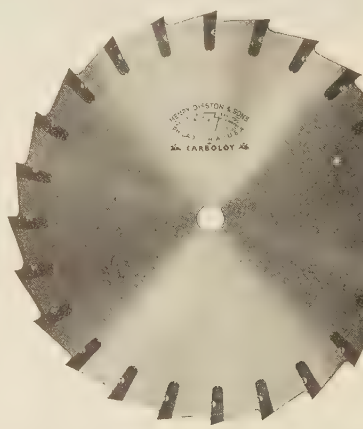

Fig. 1 Inserted-Tooth Carbide-Fitted Saw

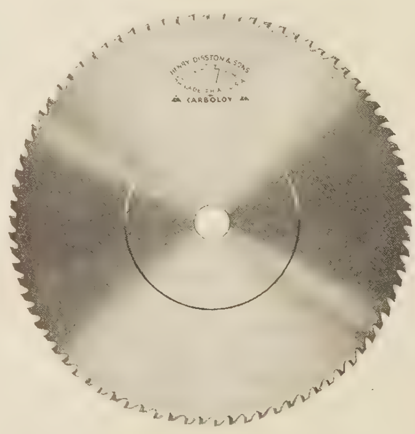

Fig. 2 Solid-Tooth Carbide-Fitted Saw

It is somewhat difficult to establish standard angles for carbide saw teeth even for definite materials, due to the fact that the position of the material to be cut relative to the saw governs the amount of rake angle required. For example, a saw used on a regular wood-saw bench for use on bakelite would require a rake angle of 12 or 15 deg on the teeth, whereas a saw used on a machine having an overhead arbor would require either a radial or zero

rake angle on the teeth, or teeth having a negative rake angle of 5 to 10 deg. In general, the tooth angles listed in Table 1 can be recommended.

In order to simplify manufacturing cost and reduce sharpening costs, the teeth of carbide-fitted saws are designed so that it is only necessary to apply the grinding or lapping wheel to the carbide tip. This is accomplished by originally grinding the angle of the steel back of the tip about 2 deg greater than the angle on the carbide, thereby eliminating the necessity for grinding or lapping the steel. The sharpening of carbide-fitted saws is a hand operation and cannot be accomplished on an automatic saw-sharpening machine. It is necessary to bring the diamond lapping wheel into contact with the carbide tip and then feed the wheel in a reciprocating manner across the tip. Fig. 8 is a diagrammatic sketch of a sharpening machine which the author recommends for sharpening carbide-fitted saws. It is possible, however, to sharpen these saws on a universal tool grinder, but it should be kept in mind that any machine used for this work must be rigid and free from end play in the spindle.[3]

TABLE 1 RECOMMENDED TOOTH FORMS AND TOOTH ANGLES FOR CUTTING DIFFERENT MATERIALS[a]

Tooth form	Material to be cut	Rake angle, deg	Top angle, deg	Alternate-bevel, deg
Straight-front	Bakelite	12	15	..
	Hard wood	25	18–20	..
	Hard rubber	15	15	..
Alternate-bevel	Cardboard	20	18	30
	Masonite	10	20	30
	Celotex	20	20	30
	Plywood	20	18	30
Square-and-advanced	Aluminum	15	15	..

[a] Recommended forms and angles to be used on saws mounted on a regular saw table with arbor below the work.

The application of cemented carbides to woodworking knives is a comparatively simple one, and if certain fundamentals are adhered to, successful performance can be assured. Fig. 9 illustrates the recommended practice for standard knives. It should be carefully noted that the included angle should not be less than 50 deg. For this reason carbide-fitted knives are not recommended for use in square heads. The carbide tip should be kept as thin as permissible so as to avoid too great a portion of unsupported tip.

The most successful setup for tongue-and-groove cutters and other similar patterns can be obtained by breaking up the cut with individual cutters rather than by attempting to apply cemented-carbide tips to the generated-type cutters. In the first place the generated-type cutter is difficult to manufacture with carbide tips, and is costly. If breakage occurs due to striking some foreign object, such as a nail or a hard loose knot the entire cutter is ruined, whereas the single cutter, on the other hand, is easy to manufacture, is considerably cheaper, and if an accident occurs the chances are that only one or two cutters will be damaged. Figs. 10 and 11 show recommended types of tongue-and-groove carbide-fitted cutters, while Fig. 12 shows the generated type of knife.

Carbide-fitted knives should not be recommended for heads requiring corrugated or serrated backs for the reason that it is practically impossible to fit them in the heads so they will track at full speed; nor can they be jointed in the head as is done with steel knives. Plain or smooth-back carbide-fitted knives can be adjusted so they will track. While these knife recommendations mean longer setup time they are based on actual experience and if followed will result in satisfactory and economical performance.

The limits to the length of cemented carbide-fitted knives are governed by the ability to manufacture straight carbide tips of thin sections. So far as intricate shapes, such as molding

TABLE 2 ECONOMIES RESULTING FROM USE OF CEMENTED CARBIDE SAWS

Material cut	Chestnut board[a]		Celotex[b]	
Type of saw	Steel	Carboloy	Steel	Carboloy
Amount of material cut per sharpening, ft	750	200000	5000	530000
Initial cost of saw	$5.04	$179	$7.50	$158
Cost of sharpening (per time)	$0.50	$18	$0.40	$15
Number of sharpenings per life of saw	30	15	25	12
Amount of material cut in total life of saw, ft	22500	3000000	125000	6360000
Total saw cost, including sharpenings	$20.04	$449	$17.50	$338
Saw cost per 1000 ft of material	$0.89	$0.149	$0.14	$0.053
Number of saw changes per 1000 ft of material cut	1.33	0.005	0.2	0.0018
Down time 3 min per change at 40 cents per hr	$0.0266	$0.0001	....	....
Down time 5 min per change at 40 cents per hr	....	....	$0.0066	$0.0000594
Total cost per 1000 ft of material cut	$0.9166	$0.1491	$0.1466	$0.053

[a] Saving per 1000 ft, disregarding increased production due to less down time = $0.7675.
[b] Saving per 1000 ft, disregarding increased production due to less down time = $0.0936.

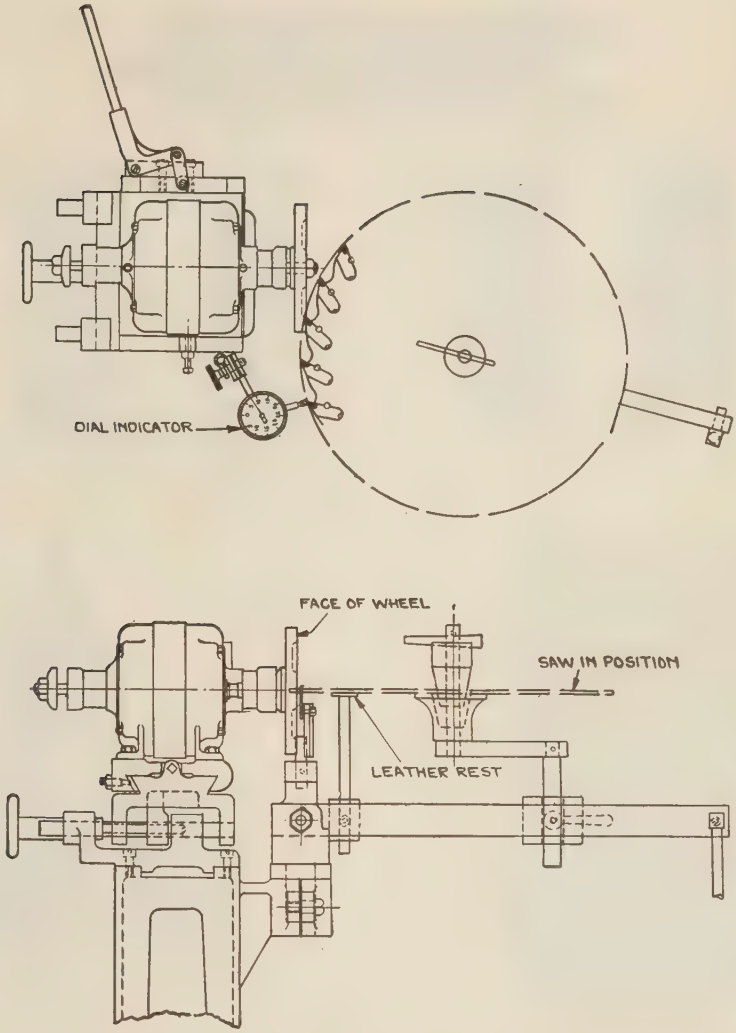

Fig. 8 Type of Grinder Recommended for Sharpening Carbide-Fitted Saws

knives, are concerned it has been proved that these can be manufactured successfully; the limiting feature being cost. Whether they can be justified depends to a great extent upon the amount of material, of a given shape, to be produced.

With carbide-fitted knives, as with saws, the sharpening costs have been greatly reduced by the introduction of bakelite wheels impregnated with diamonds. Hand sharpening of carbide-fitted knives should never be attempted. They should be held in a vise at the proper angle and sharpened on a universal or other tool grinder of rigid construction and free from loosely fitted bearings and end play in the spindle. Table 2 shows the economies to be derived from the use of cemented-carbide saws.

Some of the materials for which cemented-carbide saws and knives are recommended are: Asbestos pipe covering; bakelite, micarta, and textolite; chestnut board; corrugated container stock; celotex; enameled picture-frame stock; fiber; fireproof wood; linoleum; linoleum-covered plywood; masonite; molded brake lining; plywood and glued stock; and oriental walnut. Broader use of cemented carbide-fitted saws and knives is increasing yearly as new synthetic materials and wood substitutes of an abrasive nature are introduced, and the users of these

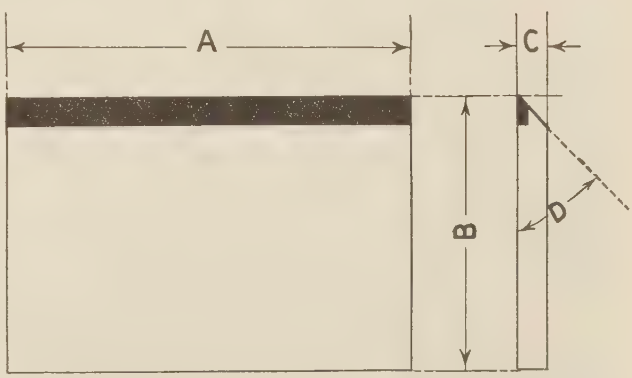

Fig. 9 Dimensions of Carbide-Fitted Knives for Wood Saws

(Dimension *A* cannot be less than 6 in.; *B* cannot be more than 5 in.; *C* cannot be less than 3/16 in.; and *D* should not be less than 50 deg. Carboloy-fitted knives are usually made as follows:

Up to 2 in. long.............. 1/4 in. thick with Carboloy 3/32 × 1/4 in.
Over 2 in. long, including 3 1/2 in. 1/4 in. thick with Carboloy 1/8 × 1/4 in.
Over 3 1/2 in. long, including 5 1/2 in. 5/16 in. thick with Carboloy 5/32 × 5/16 in.
Over 5 1/2 in. long, including 6 in. 3/8 in. thick with Carboloy 3/16 × 5/16 in.)

tools become more familiar with their use, care, and maintenance.

Cemented Carbide Saws for Woodworking

The application of cemented carbide-fitted saws and knives to ordinary woodworking has been somewhat retarded by the high initial cost and the lack of proper sharpening equipment, as well as by the inability of toolroom labor to learn the procedure. Where woods of an abrasive nature have had to be worked, or where glued stock was a large percentage of the production, some very interesting and cost-reducing applications have been made.

Little progress has been made in the application of carbide-fitted saws to straight-line rip machines for two very pertinent reasons. First, the saw must be of the inserted-tooth type with a hardened and tempered blade to withstand the strains to which the blade is subjected by the passage of warped lumber in the mechanical feed. Second, practically all straight-line ripping is for glued joints, and the cut obtained from the inserted-tooth saw is not sufficiently smooth for this purpose.

Carbide-fitted saws also are not suitable for edging veneers, because it is not possible to have the tooth spacing close enough, with the result that the cross-grain cut is usually poor, often breaking out the grain from 0.25 to 0.5 in. from the cut.

One of the most successful applications of carbide-fitted saws is for sizing plywood linoleum-covered table tops. On this application these saws are known to produce as much as 13,000 linear ft of material before requiring sharpening.

In the application of cemented carbide-fitted knives, particularly for molding (which is of glued stock probably having oriental walnut veneer), it is not necessary to have the entire intricate shape of the knife faced with the carbide. This is particularly true where there is not sufficient production to justify the initial cost. All that is necessary is to apply the carbide to a small knife or bit in the head which will take the glue line and the oriental veneer, and use high-speed-steel knives which are easily formed to shape for the balance of the molding form. Such a setup may well be applied to radio-cabinet production. The same carbide bit or knife may be used with a combination of form knives whenever it is necessary to change the pattern.

The author believes that many production shops overlook the possibility that increased production through less down time for sharpening and knife changes can be obtained by applying cemented carbide to the knife where it is required rather than attempting to apply the carbide to the entire form of the cut, which in most cases results in a very costly tool and, therefore, cannot be justified. Broader and correct use of cemented carbides in the woodworking industries will undoubtedly result in lower production costs and greater profits.

Discussion

Automatic Regulators, Their Theory and Application[1]

J. B. McMahon.[2] Automatic control at the present time is by no means a science but is in that indeterminate state where it is gradually changing over from an art to a science. The state of the art at the present time is such that any general approach to it should be such that it will very carefully include the experiences and opinions of all of the groups which are interested or may be affected; otherwise some of these groups may find themselves later on forced to engage in a vigorous struggle to establish the validity of their own experiences, viewpoints, and terminology. On that account the writer believes that a paper such as this should be representative of as wide an experience as possible and should be collective rather than individual.

There is at present no general agreement in terminology in the broad field of automatic control and no generally accepted definition of the desirable qualities of automatic regulators. The author attempts to fill this gap.

Mitereff's recent paper[3] covered the theoretical analyses of types of automatic controllers quite adequately, although he betrayed his unfamiliarity with the practical accomplishments in recent years in this field.

In the present paper, the author lists what he considers the four desirable qualities of an automatic controller, as (1) power, (2) speed, (3) sensitivity, and (4) stability. This order may not be the author's order, but he rates them all equally, so that the order of their listing is not relevant. The author also attempts to define each of these.

Of these desirable qualities, speed and power are very easy of definition. Stability is not so easy to define and is not clearly defined by the author. Stability is a combination of qualities of the controlling device which must be considered with respect to the control problem under consideration. It cannot be considered as a separate entity.

Sensitivity is capable of two definitions which are frequently confused. It may be defined as the smallest quantity of change to which the device in question is capable of responding in any degree; or it may be defined as the unit change of response per unit change of effect being measured. The author uses the first of these definitions but the second one is in very common use with respect to a control quality in a very large section of industry. Its use in this respect is not any too clearly defined and a clearer definition of its use in this respect is probably in order, but it is used in this manner and should not be disregarded.

Aside from this lack of clarity of definition by the author, the writer would like to point out that, except in specific instances, only one of these qualities listed by the author is necessary. This is power.

Speed is unnecessary in a large percentage of automatic-control installations. It should be remembered that the writer is referring to the broad general field of automatic control. The rate of change of the regulating device (valve, rheostat, motor, damper) is not important on a great many temperature-control jobs.

Stability, if considered from the standpoint of the operation of the controlling device itself, is not only unnecessary on a great many installations, but can very definitely be detrimental to successful results. To achieve successful control on many jobs and maintain the controlled effect constant, a fundamental instability must be built into the controller itself. Again, many temperature-control installations fall within this classification. In all probability more temperature controllers are sold that are fundamentally unstable than otherwise.

Sensitivity, considered from either of its definitions or both, is again a quality that must be considered with respect to the specific application under consideration. Many liquid-level controllers are made purposely insensitive from the first standpoint, having a "dead spot" purposely built into them and the increasing use of averaging-type level controllers testifies to the desirability of controllers which are intentionally built to be definitely insensitive from the second standpoint.

Therefore, it seems to the writer that instead of clarifying the subject of automatic control and its terminology, this paper[1] still further obscures it. A paper which was the result of group rather than individual effort would undoubtedly have cleared up some of the foregoing points. Also, the writer would like to reiterate that the technical handling of this subject within the next few years is going to be either very helpful or very harmful, according to the manner in which it is handled and every precaution should be taken by students of the subject to assure thorough representation of all points of view.

G. W. Smith.[4] A well-balanced criticism of the author's paper, citing those points on which agreement should be universal, those which are debatable and those which are clearly wrong, would be a considerable undertaking, far exceeding the time or space available for this discussion. Suffice it to say that there are 304 sentences in this paper, representing all three categories.

As to the first category, which in importance and general interest probably outweighs the rest; the author has done well to bring to the attention of his audience the fact that precise analysis is not only desirable but necessary for the successful application of automatic control; that behind appearance, size, popularity, and price of regulators lie factors of more basic importance, and that combined efforts of manufacturers and users to help each other see their problems alike would be advantageous. The writer thinks that greater progress must be made before a committee can successfully standardize industrial regulators according to the author's or any other classification, but nevertheless would be glad to see such a joint effort made if discussion appears to make it worth while.

The place to begin, however, is not with what the author calls the controller, or, which is worse, with the metering element, but rather with the problem to be solved. The author neglects all but two types of simple control, which he characterizes as having "process lag" and not having it. In actuality there is a much more important basis for classification, viz., the presence or absence of "self-regulation," to which the writer will refer again.

[1] Published as paper PRO-58-4, by Ed S. Smith, Jr., in the May, 1936, issue of the A.S.M.E. Transactions.

[3] "Principles Underlying the Rational Control of Automatic-Control Regulators," by S. D. Mitereff, Trans. A.S.M.E., vol. 57, May, 1935, paper FSP-57-9, p. 159.

[4] General Manager, Hagan Corporation, Pittsburgh, Pa. Mem. A.S.M.E.

Secondarily we have control problems in which (1) there is no lag between throttle movement and final effect thereof; (2) the final effect is delayed as in the author's Figs. 6 to 12, inclusive, but the first derivative of the effect is without lag; (3) the effect and its first derivatives lag, but higher derivatives do not, as discussed in Mitereff's paper;[3] and (4), there is a definite lag between movement of throttle and any palpable response whatever. The latter is common in temperature regulation. A lot has been published, publicly and privately, in this country about the metering end of automatic control, but when it comes to the matter of time lag, and excepting Mitereff's paper,[3] there seems to have been much thinking and but little thought.

From sentence 23 to sentence 301, inclusive, of the paper, there is much with which to agree, but also much with which to differ. Exception must be taken to the author's concluding remarks, from which it can be inferred, perhaps unintentionally, that maintenance and operating costs of air-operated controllers exceed those of hydraulic and electrically operated equipment. The contrary is true as to maintenance costs and, with one exception, as to operating costs as well. This of course, is especially true of combustion control.

The writer next observes that the author indicates no acquaintance with a work which has consistently been treated with a neglect that is exceeded only by its worth. Reference is made to Stein's "Regelung und Ausgleich in Dampfanlagen"[5] which, published in 1926 and followed in 1928 by the enunciation of the law of self-regulation,[6] has advanced the literature even beyond the state of the art. The writer is unable to comprehend why Messrs. Behar and Mitereff and now the author have missed or at least failed to mention this work. While ingenuity can often be displayed in devising regulators which will recognize rates of change, their complete equations of motion can only be derived by using the principles set forth by Stein.

Our American literature on control equipment suffers from what might be called "instrumentitis." Too many people have tried to solve control problems by adding a motor to a meter, and when trouble resulted, have tried to escape it by devising more and more complicated metering elements. Lame and halting regulator performance can seldom be corrected by complicating the pressure-sensitive element.

The author's discussion of "stability" represents an impossible oversimplification. His Fig. 2 may correctly represent the behavior of a meter having some inertia, if it be remembered that the second derivatives are discontinuous, or even that of a governor where inertia effects are great and self-regulation usually quite large; it does not follow that in general the hunting of a relay-type pressure regulator can be reduced by adding static friction either to the meter or to the controller. The direct contrary is in fact true as can be demonstrated theoretically with great labor, but without any difficulty experimentally.

Directly in this connection, and because of its bearing on "insensitivity," the writer must point out that the expression $x = —ky$ which the author uses frequently, cannot be correct unless the rate of outflow varies with the pressure ("self-regulation"), which is contrary to his assumptions. To see this clearly we need only replace his water jet by a reciprocating pump, or well-governed prime mover, whereupon the regulator shown in Fig. 3 of the paper will be unstable despite the zero storage lag and will require a spring inside the dashpot to make it theoretically stable. The correct expression is $dx/dt = —(1/k)(y — y_0)$ where y_0 is the valve opening at equilibrium; k is small for zero process lag and great for large process lag. The author's discussion of Fig. 3 misses the point; the equation he obtains and on which he bases his subsequent argument owes its decaying solution not to a small process lag but to the exaggerated self-regulation implied by $x = —ky$.

A proper criterion of the dead zone within which a regulator will come to rest is quite complex and must contain terms which recognize self-regulation. Putting more lap into pilot valves will not stop hunting unless there is a high degree of self-regulation, and then only if the metering element have some source of gradient or spring force. Lap, friction, and constant-speed motor operation are much alike when considered dynamically.

The author's tentative classification of regulators possesses the merits of novelty and simplicity; the writer believes it would provide a sound basis for expansion. He is, however, at a loss to account for the operation of Class XII regulator. He can only assume that the figure is incorrectly drawn.

On the basis of the author's simplifying assumptions, the performance of his Class VI regulator is identical with that of his Fig. 3 and Class IV regulator, provided that, as is always the case with the simple fluid-relay regulators shown, the pilot valve opens gradually. If one sets up the equations they will be found to have corresponding terms and to differ only in constants and not in order; the dashpot and the spring are dynamic equivalents. If the author intended Classes III and IV to typify electrically operated regulators, it would have been better so to show them. If, on the other hand, the pilot valve does open abruptly, Class IV is identical with Class III, unless there is lap.

There is some confusion in the description of the Class III regulator. It appears that the author has integrated when he should have differentiated. In his description he states that $dy/dt = \pm k$, but the curves show that $dy/dt \neq \pm k$ but rather $dy/dt = f(t)$.

This confusion becomes more evident in his description of Classes VI and VII. We present below the complete equation for a Class VII regulator; here we point out only that Class VI is inherently unstable with any finite storage lag, whether the variations in outflow are slow or fast. Changes in outflow rate brought about by external agencies lead to particular solutions of the equations; if the general solution describes an unstable motion, the regulator will not even be transiently stable.

The writer presents the author's Equation [44] as

$$b\frac{d^2y}{dt^2} + (K + c)\frac{dy}{dt} + ky = 0 \text{ (} K \text{ is spring constant)}$$

which is true only if $x = —ky$, which, in turn, is impossible in the figure shown.

When we admit the storage lag, we must set $\frac{dx}{dt} = —K'y$ and

$$b\frac{d^3x}{dt^3} + (k + c)\frac{d^2x}{dt^2} + K'y = 0 \dots\dots\dots [1]$$

There is no term in dx/dt and the equation demonstrates that the pressure variations increase with time.

Yet such regulators may be stable. Their stability is not derived from the insensitivity, which the author credits with this ability, but from factors ignored in his treatment. One such source from which stability may be derived is the variation in output rate which accompanies variation in pressure; an effect which the author explicitly rules out in his Equation [25] and consistently neglects throughout his paper. This variation supplies the missing term in dx/dt. Thus

$$\frac{dx}{dt} = —K'y — K''x \text{ .}$$

[5] "Regelung und Ausgleich in Dampfanlagen," by Th. Stein, Julius Springer, Berlin, 1926.

[6] "Selbstreglung, ein neues Gesetz der Regeltechnik," by Th. Stein, *Zeit. V.D.I.*, vol. 72, January–June, 1928, pp. 165–171, and 209–214.

where we follow the author's convention of neglecting certain constants. This leads to

$$b\frac{d^3x}{dt^3} + (bK'' + k + c)\frac{d^2x}{dt^2} + (k + c)K''\frac{dx}{dt} + K'x = 0 \quad [2]$$

Stable regulation is possible when

$$bK''^2(c + k) + K''(c + k)^2 - K'b > 0 \quad [3]$$

This is a very important relationship, and displays the advantage of decreasing the value of K', or the ratio of increment of input to movement of control valve, to the minimum consistent with the conditions of the problem.

Of course numerical evaluation of this criterion of stability would be meaningless due to the simplifying assumptions; precise results are most easily obtained by the use of Stodola's time constants.

Regulators of author's Class VII may not be stable in operation even though constructed of parts without mass, having no metering lag except that due to simple damping, and doing no work except on the dashpot. To see this qualitatively we need only imagine the reset spring as of infinite stiffness. In this case Class VII becomes equivalent to Class VI which is inherently unstable regardless of process lag so long as there is no self-regulation. Therefore, the spring stiffness must not exceed a certain finite value. On the other hand, with a reset spring of zero stiffness Class VII becomes equivalent to Class IV which is likewise unstable. Therefore, the spring stiffness must lie within certain extreme values.

Assuming a spring of optimum stiffness, it is obvious that a dashpot with zero damping will still give us a Class IV regulator which will be unstable. A dashpot with infinite damping produces a variant of Class V, which is, from the standpoint of stability, the most satisfactory of all simple regulators.

Clearly, for best results, the damping and stiffness must be selected from a range of possible values.

These somewhat vague ideas, which like the author's presentation of Class VII are purely qualitative, may be made exact. It will, the writer believes, be worth while to derive the equations of motion of regulators of this class, using time-constants where expedient, and examining more closely than does the author the validity of the assumptions. The author's symbols will be used where possible.

A start is best made with the equipment to be controlled. We replace the author's outlet jet with a reciprocating pump in order to eliminate the self-regulation of varying discharge. Then, letting Y = opening of inlet valve measured positively from the closed position; Y_e = opening of inlet valve necessary for equilibrium at any outflow, $Y_{max} = 1$ = maximum opening necessary for equilibrium with maximum outflow, X = absolute pressure in feet of water, and X_s = set value, we have

$$\frac{dX}{dt} = \frac{1}{K}(Y - Y_e) = \frac{1}{K}\,\Delta Y$$

or

$$X_s\frac{dx}{dt} = \frac{1}{K}\,y$$

where $y = \dfrac{\Delta Y}{Y_{max}}$ and $x = \dfrac{X - X_s}{X_s}$

It will be convenient to say that $X_s = 1$, and to measure pressures in terms of this unit, rather than in feet of water. With this convention

$$K\frac{dx}{dt} = y \quad [4]$$

and K is the time required to change the pressure by unity (X_s feet of water) when $\Delta Y = Y_{max} = 1$. We will call K the "storage time" and designate it by T_s where T_s is the quantitative measure of process lag in this simple type of regulation.

We next assume that our regulator and valve are such that Y_{max} is the full stroke. If, as is often the case, the valve is too large and the regulator is connected to open it fully, all constants must be corrected accordingly, and stability is proportionately more difficult to attain.

The motion z of the controller will be measured from mid position and in such units that when $z = \pm 1$, the pilot-valve ports will just be fully open, the plus sign being taken for upward movement. Then

$$K\frac{dy}{dt} = -z \quad [5]$$

is the motion of the controller. Unless the controller be sufficiently powerful, not only to position the valve accurately, but also to move the valve with a speed proportional to the pilot-valve opening, the order of our differential equations will be raised by at least one and more usually by two, and new possibilities of hunting arise. Most regulators are deficient in power in this respect.

The term K here is T_c or controller time, that is, the time required for the controller to move a full stroke (Y_{max}) with the pilot valve fully open ($z = 1$).

Combining Equations [4] and [5] of this discussion

$$T_s\,T_c\frac{d^2x}{dt^2} = -z \quad [6]$$

Designating by F, the tension in the reset spring and equating forces on the pilot valve, we get

$$x - b\frac{dz}{dt} - k_1z - F = 0 \quad [7]$$

from which the constant terms representing forces due to X_s have been canceled. We replace b by T_m, the metering time, the definition of which will almost be obvious. In numerical calculations k_1 must be expressed in units of pressure ($X_s = 1$) required to compress the spring the distance necessary to open the pilot valve. Combining Equations [6] and [7]

$$T_mT_sT_c\frac{d^3x}{dt^3} + k_1T_sT_c\frac{d^2x}{dt^2} + x - F = 0 \quad [8]$$

To determine F, let w be the position of the dashpot piston (w positive upward) measured from its equilibrium position with $z = 0$. Then

$$F = k_2(z - w) \quad [9]$$

is one expression for the spring tension, which we will substitute in Equation [8]. Hence

$$T_mT_sT_c\frac{d^3x}{dt^3} + (k_1 + k_2)\,T_sT_c\frac{d^2x}{dt^2} + x + k_2w = 0 \quad [10]$$

Another expression for F is

$$F = K\frac{d(w - cy)}{dt}$$

constant c being introduced because of the different units in which w and y are expressed. This gives

$$F = T_{d_s}\frac{dw}{dt} - T_{d_y}\frac{dy}{dt} \quad [11]$$

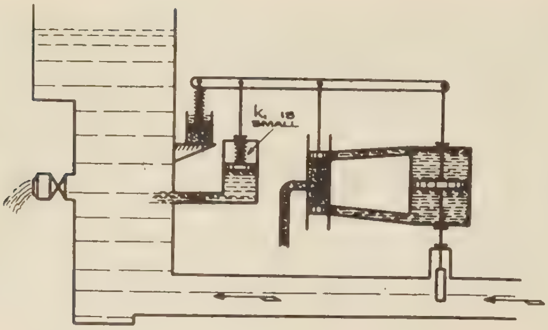

Fig. 1 Modified Class VII Pilot-Governed Regulator With a Follow-Up, and a Small Permanent Gradient, but a Larger Temporary Gradient

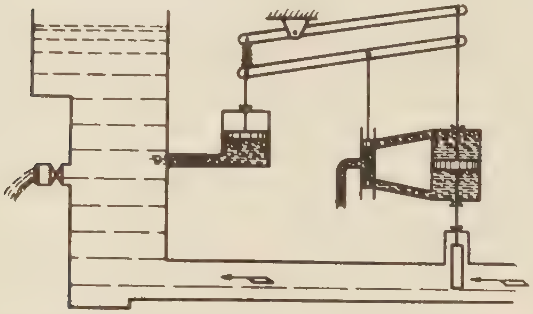

Fig. 2 Modified Class VII Regulator in Which the Gradient Is Dissipated at a Rate Inversely Proportional to T_c

where the time constants represent the times necessary for unity movement of the dashpot piston or cup while maintaining a force balancing X_s. Since $T_{dy} = cT_{ds}$, from the writer's Equations [9] and [11], and by substitution from the writer's Equations [4] and [5]

$$T_s(k_2T_c - T_{dy})\frac{d^2x}{dt^2} + T_{ds}\frac{dw}{dt} + k_2w = 0 \qquad [12]$$

Equations [10] and [12] are simultaneous equations, which may be reduced to the single equation

$$T_mT_{ds}T_sT_c\frac{d^4x}{dt^4} + T_sT_c\left[(k_1 + k_2)T_{ds} + k_2T_m\right]\frac{d^3x}{dt^3} + \left[k_1 + \frac{T_{dy}}{T_s}\right]k_2T_sT_c\frac{d^2x}{dt^2} + T_{ds}\frac{dx}{dt} + k_2x = 0 \qquad [13]$$

The condition that the solution has no positive exponential factor is

$$T_{dy} - \frac{T_mT_{ds}^2}{k_2T_s[(k_1 + k_2)\,T_{ds} + k_2T_m]} - k_2T_c\left(1 + \frac{T_m}{T_{ds}}\right) > 0 \qquad [14]$$

or

$$c - \frac{T_mT_{ds}}{k_2T_s[(k_1 + k_2)\,T_{ds} + k_2T_m]} - \frac{k_2T_c}{T_{ds}}\left(1 + \frac{T_m}{T_{ds}}\right) > 0 \qquad [14a]$$

The prime factor in determining stability is, in the final analysis, the apparently unimportant ratio between travel of dashpot cup and travel of dashpot piston. In the extreme case, where the cup is stationary and there is no self-regulation, the regulator can never be stable. This is not the same as writer's Fig. 1. The writer suggests that the author test this equation by amplifying the movement of the cup in a Class VII regulator. Equations such as these will yield much information of value in design and application.

Class VII regulators in various forms have demonstrated their usefulness over a period of several years. Two modified forms are shown in Figs. 1 and 2 of this discussion. Of these, Fig. 1 is in many respects an improvement; in common with Class VII and notwithstanding the author's disclaimer, such regulators possess the ability to overswing the control point and return gradually without hunting. This ability is lacking in the regulator shown in Fig. 2 of this discussion, but in many applications it is the full equivalent of Class VII.

John J. Grebe.[7] Those familiar with the control problems in industry have met the endless confusion of terms and explanations that accompany the discussions of what various instruments do and how they do it.

All the work of control instruments is presented as more or less of a mystery. Each manufacturer uses a different terminology, and often deliberately chooses different phrases to avoid the appearance that a given control effect might be similar to that of another manufacturer. As a result, when any one talks with a person versed in the art of automatic control it is necessary to use three or four synonyms with each specialized word in the hope that one of them will be understood. This was necessary in a paper[8] presented to the American Institute of Chemical Engineers in 1933, and reedited by T. R. Olive,[9] and found even more necessary in the oral discussion of the paper, which ended with a plea for some sort of standardization of terminology that might possibly become a basis for a better understanding.

Anyone who realizes what the proper continuous automatic control can do for industry, will never be satisfied with anything less than a thorough understanding and application of this phase of engineering.

H. H. Dow in his Perkins Medal address[10] made a very clear statement of this picture. He was an early pioneer in the development of automatic-control apparatus, and was a great inspiration to the application of this work to processes and apparatus at The Dow Chemical Company.

The writer believes that there is no one individual item of standardization or correlation in which the A.S.M.E. can become more useful and valuable than in this particular development. It applies to every engineering project dealt with in our publications and papers, practically all engineering improvements and developments being based on better and more versatile control. A great deal toward unification has been accomplished by M. F. Béhar,[11] H. L. Young and T. R. Olive[12] and by the author of the paper under discussion.

The explicit and complete information given by the author on each of the various classes of regulators makes it possible to get a much better picture of the working principles of the types of control with which we have not been familiar. It is easy

now to correlate the various classes in terms of what they do rather than in terms of the way they do it, with all the experience we have had on our own control equipment, built to meet extreme requirements.

The writer believes that all control effects can be classified under the four basic principles listed as the headings of Table 1.

Metered Control. First is the metered control, that is, the integrating, ratio, or proportioning control, all of which are terms that are used to represent the methods by which various apparatus work in which the flow of the controlled quantity is caused to be regulated by the quantity of the material passed through, independent of the end result. This quantity may be variable, so that, as the primary flow changes the secondary flow must be related or proportioned. This is generally used in combustion work.

Deviation Control. The second main subdivision in the methods of control is the deviation control, also called proportional control, or as by the author, modulating, noncorresponding, or floating control. The deviation control, however, can be very crude and often amounts to nothing more or less than an open-and-shut control which operates the valve fully open and fully closed, and sometimes improved by the use of a by-pass or the like to take away the severity of the changes.

The next improvement in deviation control is to have it opening and closing as the meter calls for more or less, generally at a fixed rate of opening and closing, or an on-and-off control, or a valve-moving mechanism, such as a hydraulic relay or motor-operated valve.

The final improvement in deviation control that makes it a good proportional, modulating or noncorresponding control, is one in which the rate of action of the valve closing or opening it is proportional to the deviation, and which always comes to rest at the very same meter point (point control, one type of floating regulator, algebraic difference).

Many control devices, because of the particular apparatus used, have a drooping characteristic similar to the drooping of the voltages of d-c generators, which the author calls corresponding control. This is a serious criticism of many control apparatus, since that particular property is not desired, except under special conditions where control units are operated in parallel.

This is counteracted very often by what some people call the reset or follow-up with dashpot. This compensation can be taken care of either in the meter or in the responsive instrument itself, or in combination with the control motor, such as shown in the author's paper where the dashpot accomplishes this work.

Storage-Lag Pacer Control. The third method of control is rate, anticipatory, or storage-lag pacer, or process, or capacity, or inventory-lag compensator. This control effect is generally added to deviation control or the combination with metered and deviation control, in order to increase the speed of correction when the indicator is going away from the right value at a rapid rate and to anticipate overshooting when the indicator is approaching the right value at a rapid rate.

This control effect is proportional to the rate of change of the indication, and is typified by Class VII, which incorporates a very high type of deviation control, which is accurately proportioned to the deviation without drooping characteristics because of the dashpot; it is very satisfactory because of the storage-lag pacer. This combination can be made to work on practically any control job, especially if the storage-lag pacer is emphasized sufficiently so that the rate of correction is very high when the deviation is first detected and then tapers off rapidly to the correct valve setting over a period of time roughly proportional to the inventory (capacity, storage) lag.

This storage-lag pacer also runs through a whole range of refinements, sometimes being as crude as in the case of temperature control in which by artificial means the effective temperature around the control unit is increased by various methods, so that the temperature control will anticipate by building up heat in the system before it finally reaches the sensitive element and shuts off the flow of heat to prevent overshooting.

An improved type is shown by the author in his Classes X and XI, where the control point is varied over a period of time proportional to the capacity or storage lag of the system. But the best type is where the sensitive element is located so as to get the effect of the change produced as soon as possible and then actuates the control, not only according to the actual position the indicator has reached, but also according to the rate of change. Generally it is very cumbersome and involves considerable amount of mechanical equipment to have the storage-lag pacer affected by the motion of the final control actuator as in the case of the illustrations given in the paper; but, of course, it can be done that way.

Time-Lag Compensator Control. The fourth and final control method is the time-lag compensator (response-lag-pacer method, transfer, indication, correction, velocity distance, lag compensator) which the writer has called damping control. In order to have this free of the disadvantages pointed out by Mr. Smith in his discussion of Class XII regulators, it should also have in it the ability to delay its action for a time proportional to the amount of the lag.

The writer believes that the only error to be found in the paper is in connection with the discussion on the Class XII regulator, (pilot-governed, phase-shift with reversal at control point). The description is that of a storage-lag pacer or rate control in which the rate of change of setting of the valve is determined by a storage-lag pacer control built into the sensitive element or meter, rather than in combination with the control members or actuators. The illustration given does not agree with the description; first, because it works backward the way it is shown, and second, because it shows a direct-operated valve where the position of the valve is directly determined by the position of the meter, rather than the rate of change of the valve setting being determined by the position of the meter.

If, in the diagram below Fig. 17 of the paper, the dotted line represents the rate at which the correction is taking place, and the solid line represents the rate of flow or the opening of the valve, as in all the other cases, or y of all the other curves, then it is a storage-lag pacer. On the other hand, if one rebuilds the unit as shown in Fig. 3 of this discussion so that the dotted line of the author's Fig. 17 represents the position of the valve or y, then the control effect might be called the delayed-action damping control previously described by the writer,[8] if it is independent of the rate of change, but proportionate to the second derivative of X, and effective only for a period of time measured by the straight time lag.

This method of control also has a whole range of gradations of refinements. The crudest form is called the "kicker" in which an arbitrary overshot is passed momentarily to make up for part of the undercompensated flow that has passed the valve between the time the change occurred and the time that the detector and controller finally do something about it.

In order to make the response-lag compensator satisfactory, and to avoid extreme variations in flow as well as to make its effect proportional to the amount of the lag, and proportional to the deviation, it is necessary to build into it a means for delaying its action. The overbalanced flow then compensates for the amount of uncorrected flow having passed through for an accurately proportioned period of time. It makes the difference between the diagram as shown in the interpretation[9] of our paper[8] by T. R. Olive and the effect of the "kicker." It also makes it possible to get the benefit of cyclical operation or intermittently

TABLE 1 GRADATION CHART OF THE FOUR BASIC CONSTITUENTS OF CONTROL[a]

		I Metered	*II* Deviation	*III* Storage-lag pacer	*IV* Time-lag compensator
		Ratio Proportioning Integrating	Proportional Noncorresponding Floating Modulating	Capacity or inventory lag compensator Anticipatory Rate control	Response-lag pacer Damping control Transfer, indication, and correction lag compen.
100 *A*	All that is available	Metered flow prop. to rate of change + rate of flow + state of inventory	Proportional Noncorresponding Dashpot Point control Algebraic difference	Reset spring on follow-up	Delayed-action damping control
60 *E*	Elemental form of the effect	Metered flow prop. to demand or flow rate + state of inventory	Corresponding Band control tapered, fixed, drooping characteristics	Follow-up	Damping
30 *I*	Imperfect Inaccurately proportioned	Metered flow prop. to state of inventory, e.g., steam pressure	Opening-closing On-off High-low Open-shut	Roughly modifying, indication or control point to overemphasize effect of changes	Kicker
0 0	Omitted	Not incorporated in control system.			
U	Unsatisfactory because of negative effect	Many control apparatus are too abrupt or too slow, i.e., air-operated units often have so much instrument capacity lag and time lag that some of their good points are lost by bad ones.			
—30		Inaccurate	Jerky	Gradual	Late

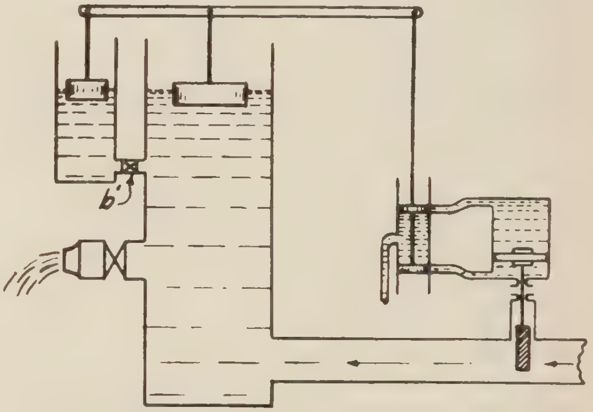

FIG. 3 CLASS XII REGULATOR FOR NONDEVIATION CORRESPONDING CONTROL

[This regulator, revised from the author's Fig. 17 now becomes another mechanical form of Class VII control.]

operated control, and yet have the apparatus at the same time able to respond to any new changes that come about during the period otherwise ineffective.

A simple way of determining the difference between the storage-lag pacer and the time-lag compensator, is to realize that the first is primarily sensitive to the rate of change. It can anticipate overshooting, shifts the phase and is capable of changing the control point so as to anticipate the condition that will come about when the changes that have been made will have had time to affect the inventory of the system. The straight time-lag compensator acts to give an overcorrection for a period of time proportional to the time lag and regardless of the amount of inventory or storage lag. Depending on conditions it frequently actually calls for less and reduces the valve opening to a smaller flow after having passed a compensating slug while the indication or meter still is on its outward excursion and calling for increasing quantities.

We have had controls where, under actual working conditions, in order to get the best results it was necessary for the control to open up a valve due to rate control, while the reading was still on the other side but approaching the control point rapidly, and while the deviation or proportional control was calling for less. Then while the latter plus the storage-lag pacer was calling for more, the time-lag compensator actually overpowered both of these control effects and called for less, so that by the end of the excursion away from the right value, and while calling for more according to the deflection, all of the regulating had been done and the various control effects neutralized one another so that on the way back to the control point practically no action was being taken. Then after some time, when the effect of all this got to the sensitive element the reading was very close to right.

With the help of this paper[1] by Mr. Smith it has been much easier to prepare Table 1 of this discussion which shows the four control effects, their various stages of perfection and interdependence, and the combinations and permutations of these various effects that are possible in any one control unit. Then if we remember that any one control unit of a whole system, in itself often requires compensation for its own storage or time lag, or both, it is very easy to see that the number of combinations is infinite. Obviously, any of these control effects can be carried out either by direct action, by pilot valves, relays, electromagnetic units, photoelectric devices, etc.

For simplicity in correlating these points, each of the various classes of controllers shown by Mr. Smith, plus the one shown in Fig. 3 of this discussion, is listed in Table 2 of this discussion with the various control effects that enter into each operation and roughly the degree of perfection of each of these.

To illustrate the development of Tables 1 and 2 of this discussion let us analyze the Class VII regulator.

Factor I. Metered control, is not shown in Fig. 12 of the paper. It does not refer to any proportioning or metering device used to keep the flow through the valve proportional to the demand independent of the level of the reservoir. This function can be added when desired. It rates zero for the control factor that is omitted.

Factor II. Deviation control is embodied in the highest and best type. Each change in level calls for a change in the setting of a pilot valve proportional to the amount of deviation regardless of the total demand, the level reading remains the same. There is no throttling range or drooping characteristic. It controls to a point, and is rated *A* under *II*. The action of the pilot valve is accumulative or integrating. The change in the position of the pilot or the sensitive element does not cause a direct and corresponding change in the control valve, but instead determines the amount of fluid that will accumulate back of the piston to move the valve to its new position. It uses a noncompressible fluid for quick, accurate, and continuous transmission of the control impulses. Hence, reference to *iplA* for Class VII regulators under factor *II* stands for an integrating pilot-operated liquid-pressure deviation control that does all it can do to keep the reading at a point regardless of the demand.

Factor III. Storage-lag pacer effect is obtained by a dashpot in which the rate of change of level reading is used, not only to get an idea of the actual change in demand which occurs, even though it is buffered by the inventory of the system, but also to overemphasize the effect of the rate of change. Overshooting of the control point is anticipated and counteracted, so that, in effect, the control operates as though the reading were at the point at which it will arrive if the constants of the system do not change in the meantime. Therefore, in Table 2 rates under *II*, *iplA*, for an integrating, pilot-operated, liquid-pressure-powered, storage-lag pacer.

Factor IV. Time-lag compensation is not embodied in Fig. 12 of the paper. There is no means shown that would make it possible to compensate for the undercorrected flow that passed before the control equipment was able to reach the new setting. This requires a control factor which will call for a change in supply in excess of the required change, for period of time partly determined by the response lag, after which the more correct value of flow is established. All this should be done within the time required for the reading to make its outward excursion. This eliminates cycling entirely.

While good engineering aims to reduce this lag to the minimum, so that the need for compensation is reduced, there generally remains enough to cause loss or inefficiency. This is particularly important with the modern tendency in engineering for less and less inventory and smaller, more responsive units.

A. F. Spitzglass.[13] Mr. Smith has mentioned the need for clarification and simplification in the field of automatic regulation. In this fast-changing art, with its ever-expanding scope and ever increasing boldness of application, development has occurred spontaneously from many independent sources. Each drew on its own background of experience. The turbogovernor designer created highly refined hydraulic mechanisms. The electrical engineer attacked the problem in terms of motors and contacts. Others drew on their experience in the gas fields and developed pneumatic operation. The theoretician thought in terms of vibration phenomena, the plant engineer in terms of his process.

Quite naturally each carried along the nomenclature of the art from which the inspiration was drawn and a baffling multiplicity of terms exists as a result. Today the trend is toward standardization and to a more composite understanding. The confusion in nomenclature, however, still extends to the conceptions and definitions and renders the task of presenting to industry a straightforward presentation well-nigh impossible.

We must therefore compliment the author for presenting for general consideration a tentative starting point. Due to the many points of view his classification will not satisfy many of his contemporaries. Even in the author's mind it is not as important that it should do so, as that it should stimulate activity toward ultimate simplification and clarification.

Individual effort is insufficient to cope with this task of standardization. The field of regulation is capable of embracing the entire range of industrial processes. Certain generalizations are possible and in an accompanying discussion by Dr. M. J. Zucrow[14] this phase of the problem is most aptly discussed. These generalizations are purely mathematical, however, and while they form the very groundwork and background of the concept of regulation, they must be complemented by analyses extending to the specific processes of industry in order to be utilized to practical advantage.

Mr. Smith has carried this program a distinct step forward with an analysis of regulator types. This analysis, while useful, will give rise to much controversy, but the very existence of this difference of opinion will emphasize the author's main point that the necessity of an authoritative effort to clarify the entire problem. Every branch of engineering is involved and the problem can only be handled by a group truly general in scope. A special A.S.M.E. Committee could accomplish much by making it possible for all those interested in controllers to use the same terminology, even though they be in widely divergent fields.

The writer has found several approaches to the problem of classification of automatic regulators. Mode of application, ultimate result, metering response, stabilizing mechanism, inherent stability, power medium utilized, and economic factors; from any of these considerations a new classification arises. Inevitably these classifications overlap and contradict each other to such an extent that we must resort to the convenient mechanism of "simplifying assumptions" in order to fit the pieces of our puzzle into the simplest pattern.

For example, it is very convenient in regulator theory to assume massless power linkages, and incompressible operating fluids. But these factors are only negligible in liquid-operated regulators, while in pneumatic devices they form an important factor and even act as a limitation to the use of air as a power medium for regulators. Therefore, any classification of regulators must be cross-classified with relation to the power medium utilized, as it is very possible that a regulator which, when actuated by an incompressible fluid will be stable for a given control operation will be unstable if actuated by a compressible gas should the speed of operation required be sufficient to create an appreciable inertia in the power linkages.

Further amplification of the author's very general statement in the abstract of the paper that "sensitivity, speed, power, stability are pertinent variables of automatic regulators" would be of great value. There is a wide divergence of opinion on the relative importance of these four factors, and it is entirely due to an attempt to consider the regulator apart from its application. Thus, there are some control applications in which it is important that the sensitivity be of a low order in order to give a simple and stable control, while in the regulation of a suction main on an open-hearth furnace pressure very high degrees of sensitivity are necessary.

Speed is another such contradictory variable since stable regulation can be obtained by increasing the speed of the regulator in cases where no metering lag exists or by decreasing it where a

[13] Vice-President, Republic Flow Meters Company, Chicago, Ill. Mem. A.S.M.E.

metering lag does exist. In the latter case the degrees in speed would cause a consequent increase in the sensitivity and accuracy of regulation.

Stability is a function of all the other elements in the regulator plus all the variable elements in the application. The Class VII regulator is shown to be stable for a very wide variety of conditions, but any specific regulator of this class must be analyzed further to answer the question: Will the regulator itself have the inherent speed, sensitivity, and power necessary to perform the cycle of operations indicated on its characteristic curve? It is not merely refinement of manufacture that the writer has in mind but actual limitation due to class of metering device or class of power medium.

Referring to the specific classification adopted by Mr. Smith, the writer's experience has been for the most part with regulators of Classes V, VI, VII, and XII.

Of these, Class V is a very common form of regulator giving "band control." Case VI can be considered a special case of Class VII, in which the reset spring of the latter is increased to the point of rigidity. Obviously, therefore, it is quite limited in application as compared to Class VII.

Again Class XII can be reproduced as a special case of Class VII in which the reset spring is weakened to such an extent that the piston must *overswing* its control point in order to compress (or tension) the spring enough to create the follow-up pressure that retards the motion of the regulator. Furthermore, Class VII with a locked dashpot becomes Class V, while with a wide-open dashpot it becomes either Class IV or Class III, depending upon the characteristic of the meter. Thus, Class VII, by virtue of its wide field of application, occupies a unique position in this classification and Mr. Smith is fully justified in treating the Class VII regulator as a basis of comparison with other classes of regulators. In the ultimate form in which the suggested report would be presented, it would be very simple to demonstrate how the Class VII can be used in the same manner as many of the other classes of regulators and this would form a logical extension of the mathematical treatment Mr. Smith has given to the subject of stability.

Concluding, it is sincerely hoped that these questions will become the subject for a disinterested study on the part of a proper A.S.M.E. committee. An authorized report on automatic regulation would give a common starting ground that is very sadly needed if we are to make the art of regulation keep pace with the demands being made upon it by industry.

M. J. Zucrow.[14] There can be no controversy over Mr. Smith's allegation that the literature pertaining to the art of regulation by electrical and mechanical devices has been outstripped by the art itself. The only qualification that might be made is that the lack one finds in the technical press of this country exists to a smaller extent in such European countries as Germany. To the writer's knowledge, the only detailed discussions of the mathematical theory underlying the coordinated regulation of several variables are those written by German engineers. That a wide dissemination of a similar literature in this country would be valuable to all parties interested in this subject cannot be doubted. Furthermore, one cannot deny that there is a lack of definition and a looseness in the current use of the terminology. This is not limited to the statements of the manufacturers' advertising departments, but is found among those of engineers. If the development of no other phase of the literature be sponsored by a special research committee of the A.S.M.E. that of standardizing and defining the terminology would be a worthy undertaking for such a body. Their recommendations will give authority to the terms finally adopted and assist materially in the development of a common language which all can understand. In this regard, Mr. Smith has made an excellent beginning by presenting a list of some of the more common terms together with their definitions. The writer is pleased to note that these definitions are merely suggestive. Definitions are fathered by the point of view of the definer. Perhaps, if they were developed from a basis founded upon an analysis of what is involved in the problem of regulating the value of a variable, to a definition of the functional parts of the mechanism, the results might have a more general applicability.[15]

[14] Republic Flow Meters Company, Chicago, Ill. Mem. A.S.M.E.

The regulation problem may be analyzed from a different, and perhaps more general, viewpoint than that adopted by the author. To illustrate this mode of analysis, the writer will discuss the general problem of a steam-pressure regulation, such as that shown schematically in Fig. 4 of this discussion. The remarks will be confined to regulators which operate with auxiliary power supply; that is, pilot-operated regulation. The problem is to maintain the pressure ahead of the demand valve B at a constant value.

The mathematical procedure involves certain simplifying assumptions. The pressure regulator is assumed to be a massless device; this is allowable because special means can be employed

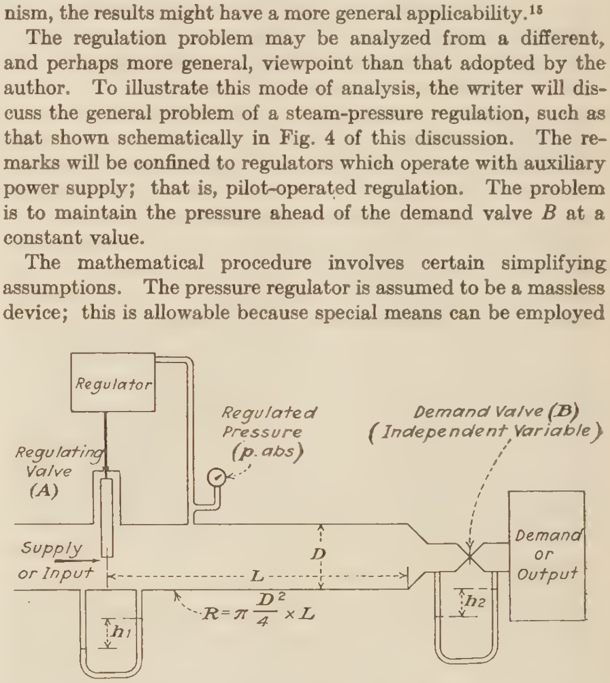

Fig. 4 Simple Pressure-Regulating System

to keep its mass and stroke small, and to operate successfully the regulator does not require any mass. In the usual case, the mass of the regulator is merely the weight of the transfer lever connecting the power cylinder to the pilot valve.

The system shown in Fig. 4 of this discussion will be at rest only when the steam demand (heat output) and steam supply (heat input) are balanced. The steam pressure which is to be maintained constant by the regulated valve is a measure of the storage of the system, and it is the duty of the steam-pressure regulation to maintain the storage at a constant value. While one can conceive of a regulation process in which a regulator element measures the demand and instantaneously positions the regulating valve to its corresponding position, so that no vibrations occur, this is not the usual case. Ordinarily the difference between the supply- and demand-steam flows acts upon the storage condition of the system, which in its turn reacts back on the regulator. The entire process involves a time lag between the change in the storage and the corrective action of the regulator, so that the regulated system passes into the new equilibrium condition with a vibration. The equation of the vibration is influenced, in general by the characteristics of the change in the demand, the particular fluid flowing in the pipe, the pressure drops h_1 and h_2 and the regulator itself. In the case presented

[15] "Regelung wärmetechnischer Grössen," Verfasser: J. Krönert, *Archiv. für Technisches Messen*, J 060-1, Reference T-109, August, 1935.

in Fig. 4 of this discussion, no specific characteristics have been assigned to either the regulator or the demand. The demand valve B may be hand-actuated or operated mechanically. The demand steam flow may be utilized in such units as a turbine, accumulator, or a steam hammer. Consequently, the changes in demand may be of a uniform character, sudden or cyclic. Its specific characteristic will have an influence on the equation for the steam demand. Only the simplest case will be discussed.

Let W_0 = the steam consumption when the system is at rest (the normal supply) at the time $t = 0$; W_{max} = the maximum quantity of steam which is controlled by the regulator; W = the steam flow at any instant t; t = any time during the period of opening (it will be assumed that the valve opening is a linear function of its movement, and is opened with uniform velocity); and T_0 = the time which would elapse before the maximum steam flow past the regulator valve would be taken up (or shut off) by operating the demand valve B. For want of a better name this time will be called the "demand period."

To illustrate the significance of the time T_0, suppose that the valve B is operated manually. The process of opening the valve might be to alternately and gradually increase the valve opening for 1 sec, and wait 1 sec to note the effect, then to repeat this process until the desired quantity of steam flows through the valve. On the other hand, the valve might be opened continuously to increase the steam flow at a uniform rate. These two cases are illustrated in Fig. 5 of this discussion, and the case shown at the right is assumed to apply to the writer's discussion. In

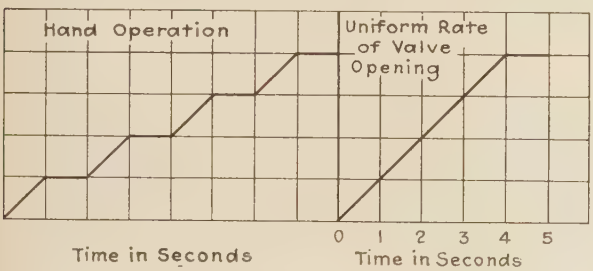

FIG. 5 DEMAND-FLOW CURVES

the latter case the steam is taken up at a uniform rate and the equation for the rate of steam flow past the regulating valve is

$$W = W_0 + \frac{t}{T_0} W_{max} \qquad [15]$$

If the steam supply has to be changed to meet a sudden demand, the equation for the steam demand would be

$$W = W_0 + xW_m \qquad [16]$$

where x is that fraction of the maximum steam flow W_m which is required with a rapidity so great that it may be termed a "sudden demand." Obviously, a steam demand defined by Equation [15] will have a different reaction on the regulation process from one defined by either Equation [16] or their combination.[5] It can be shown that in general the steam-flow equation for a uniform and sudden demand occurring simultaneously is

$$W_2 = W_0 + (t/T_0 + x)W_{max} \qquad [17]$$

Let p = the value of the absolute pressure for which the regulator is set; Δp = a deviation from p; $\phi = \Delta p/p$ = the departure from normality; $\delta = \phi_{max}$ (Δp_{max} is the pressure deviation for which the regulator has its full operating velocity); m = the position of the power piston at time t; $M = m/\phi_{max}$; and θ = ϕ/δ. Let the rate of steam flow through the regulating valve be assumed to be proportional to the valve position; that is, to the position m of the power piston. Then the maximum flow W_{max} corresponds to M_{max}, and a change in steam flow ΔW corresponds to some value of m. Let W_1 be the rate of steam flow through the regulating valve, then

$$W_1 = W_0 + MW_{max} \qquad [17a]$$

Hence, if the demand flow be less than the supply flow, then the pressure in the pipe between the valves A and B will rise; and vice versa. If the volume of this pipe is V it will require dt seconds to fill it with the unbalanced flow $W_1 - W_2 = \Delta W$. The rise in pressure causes a change in the steam density ρ amounting to $d\rho$. The storage is, therefore, increased by the weight of steam $Vd\rho$. Hence

$$(W_1 - W_2)\, dt = \Delta W\, dt = Vd\rho \qquad [18]$$

For the relatively small pressure changes involved, it may be assumed that the change in the steam density is proportional to the corresponding change in steam pressure; that is, $d\rho/\rho = dp/p$. Hence

$$\Delta W\, dt = V\rho\, d\rho/\rho = V\rho\, dp/p = R\, dp/p \qquad [19]$$

where $R = V\rho$ = the steam content of the pipe at time t.
But by definition

$$d\phi = dp/p, \text{ so that } dp = pd\phi \qquad [20]$$

Hence

$$\Delta W\, dt = Rd\phi \qquad [21]$$

Or from Equations [17a] and [18]

$$M = \frac{R}{W_{max}} \frac{d\phi}{dt} + \frac{t}{T_0} + x \qquad [22]$$

It is seen that the dimension of R/W_{max} is that of time. Physically, R/W_{max} is the time required for the maximum rate of steam flow to fill the piping annexed to the regulating valve. Let this time be called the "application lag" and be denoted by T_a. Substituting for R/W_{max} in Equation [22]

$$M = \pm T_a \frac{d\phi}{dt} + \frac{t}{T_0} + x \qquad [23]$$

Equation [23] is the equation for the pressure change; the sign preceding $T_a(d\phi/dt)$ is positive when the pressure increases, and negative when it decreases. This equation is perfectly general and is independent of any special regulator construction. It involves the "application lag" of the system, the position of the power piston, and the characteristics of the change in the steam demand. To establish the complete equation of motion for a given case of regulation, the chain of circumstances caused by a "departure from normality" must be analyzed for the specific regulator.[5]

In comparing the suitability of different regulators to any application, three phases of the regulation process are of major interest: (1) The conditions underlying a stable regulation, that is, one in which oscillations are quickly damped out. (2) The value of the maximum departure from normality which will occur with a definite change in demand. (3) The period of the regulation process; for this should not exceed a practical allowable value.

These phases can be investigated by applying Equations [24] of this discussion to the speicfic problem. Ordinarily the result will be in the form of a differential equation of the form

$$\left.\begin{array}{l} C_0 \dfrac{d^2\phi}{dt^2} + C_1 \dfrac{d\phi}{dt} + C_2\phi = 0 \\ C_0 \dfrac{d^3\phi}{dt^3} + C_1 \dfrac{d^2\phi}{dt^2} + C_2 \dfrac{d\phi}{dt} + C_3\phi = 0 \\ \cdots\cdots\cdots\cdots\cdots\cdots \\ C_0 \dfrac{d^n\phi}{dt^n} + C_1 \dfrac{d^{n-1}\phi}{dt^{n-1}} + \cdots\cdots + C_n\phi = 0 \end{array}\right\} \quad \ldots\ldots [24]$$

The relationships between the constants $C_0, C_1, \ldots\ldots C_n$ determine the stability of the regulation.[16]

Mr. Smith chose the first of Equations [24] to illustrate the vibratory characteristics of a regulation process. It might be well to amplify his remarks. The regulation equation can be written in the form

$$\frac{d^2\phi}{dt^2} + a\frac{d\phi}{dt} + b\phi = 0 \quad \ldots\ldots [25]$$

The corresponding characteristic equation, found by letting $\phi = e^{ct}$, is

$$c^2 + ac + b = 0 \quad \ldots\ldots [26]$$

The solution of the Equation [26] is

$$c = -\frac{a}{2} \pm \sqrt{\frac{a^2}{4} - b} \quad \ldots\ldots [27]$$

If $a^2/4 > b$, the radical in Equation [27] has a real value, but if $a^2/4 < b$ it has an imaginary value.[17] The latter is the case being considered; when $a^2/4 > b$ the result is aperiodic.[18] When $a^2/4 < b$ the solution of Equation [25] is

$$\phi = e^{-\frac{a}{2}t}(C_1 \sin \omega t + C_2 \cos \omega t) \quad \ldots\ldots [28]$$

where ω is the angular velocity of the cycle in radians per sec (see author's Equation [1]). The values of the constants of integration C_1 and C_2 are found from the initial conditions.

It has been shown by the author that the value of factor $e^{-\frac{a}{2}t}$ determines the degree of damping. The rate of damping depends upon the magnitude of a, and the amplitude of vibration diminishes after every cycle in the ratio[19]

$$e^{-\frac{a}{2}t} : 1$$

If the amplitude of the first half cycle is assumed to be $A_1 = 1$, then the decrease in the amplitude A_2 for the second half cycle will be a measure of the damping. The time for a one-half cycle is

$$\omega = \sqrt{b - \frac{a^2}{4}}$$

so that

$$t = \frac{\pi}{\omega} = \frac{\pi}{\sqrt{b - \frac{a^2}{4}}} \quad \ldots\ldots [29]$$

[16] "Regelung der Kraftmaschinen," by W. Tolle, third edition, Julius Springer, 1909.

[17] "Functions of a Complex Variable," by E. J. Townsend, Henry Holt and Company, New York, 1915.

[18] "Advanced Calculus," by W. Osgood, The Macmillan Company, New York, N. Y., 1922.

[19] "Vibration Problems in Engineering," by S. Timoshenko, D. Van Nostrand Company, Inc., New York, N. Y., 1928.

A_2 is the value of ϕ when $t = \dfrac{\pi}{\sqrt{b - \frac{a^2}{4}}}$

$$A_2 = e^{-\frac{\pi}{\sqrt{\frac{4b}{a^2} - 1}}} \quad \ldots\ldots [30]$$

From Equation [30] of this discussion it is seen that the magnitude of A_2 depends upon the ratio $k = a/2\sqrt{b}$. The per cent reduction in amplitude for the one-half cycle is

$$P_A = 100\left(\frac{A_1 - A_2}{A_1}\right) = 100\,(1 - A_2) \quad \ldots\ldots [31]$$

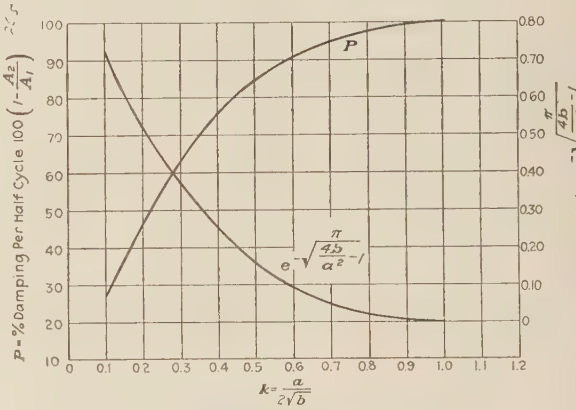

Fig. 6 Damping and Amplitude Curves

Now a and b in the criterion $k = a/2\sqrt{b}$ have the following significance. If b be considered to be the damping required for an aperiodic regulation (condition if $a^2/4 > b$) and a the actual damping, then k is the ratio of the actual damping to the aperiodic damping. This means for the vibration decay to be rapid, the value of k must be large. Fig. 6 of this discussion illustrates P_A and A_2 as functions of k.

Now the damping of a regulation may arise in the more usual cases from three sources:[20] (*I*) Inherent damping of the system itself. (*II*) Damping due to the flow of fluid through the pipe producing a pressure drop between the measuring station and the demand valve. (*III*) Damping due to a mechanical follow-up. These three types of damping depend on δ, T_a and T_s; where T_s is the regulator period, that is, the time required to move the piston its full stroke with the pilot valve wide open. Now δ is related to the sensitivity of the regulator and $1/T_s$ is the regulator speed. Furthermore (*I*) and (*II*) depend upon the load factor $z = W/W_{max}$. The specific equations for $k = a/2\sqrt{b}$ for (*I*), (*II*), and (*III*) are, however, different. They have the following forms

$$k_a \propto z\sqrt{\left(\delta\frac{T_s}{T_a}\right)} \quad \ldots\ldots [31a]$$

$$k_b \propto z\sqrt{\left(\frac{T_a}{\delta T_s}\right)} \quad \ldots\ldots [31b]$$

$$k_c \propto \sqrt{\left(\frac{T_a}{\delta T_s}\right)} \quad \ldots\ldots [31c]$$

Since k must be large, about 0.5 at least, to give stability, it is seen that the damping effects (*I*) and (*II*) are inconsequential for

[20] "Regler für Druck und Menge," by G. Wünsch, R. Oldenbourg, Münich, Germany, 1930.

small load factors, or if T_a is large. Since the damping due to a mechanical follow-up is independent of the load, it is apparent that regulators without such a follow-up must be restricted in their application.

Mr. Smith has pointed out that power, speed, sensitivity, and stability are the requirements for good regulation. That the regulator must have ample power to overcome the resistances it is to encounter needs no further comment; it is a consideration, however, in applying direct-operating regulators. The remaining requirements are not independent of each other as an examination of Equations [31] of this discussion quickly reveals.

The classification of regulators presented by Mr. Smith is interesting and instructive. There is no doubt in the writer's mind that some organization of the knowledge regarding the construction and behavior of regulators, whether by classifying the devices as the author has done or from some different viewpoint, would be valuable to all who are interested in this art. Any scheme which brings out clearly the behavior of the different types of devices with emphasis upon their suitability for different applications together with their limitations should be welcome. A regulation problem has to be engineered, and any information which will assist the customer in determining exactly what he will be getting if he purchases one device or another will be of value to all.

S. D. Mitereff.[21] The writer is under the impression that while the paper of Mr. Smith is valuable in many respects, it does very little to clarify the problem of automatic control in its basic aspects. It might be helpful, therefore, to present the fundamental situation from an angle which will permit a better visualization of factors involved.

A control installation consisting of inflow, outflow, and storage can be represented by a dynamically equivalent layout shown in Fig. 7 of this discussion. This layout consists of a massless carriage M disturbed by a random force F_x, damped by the dashpot O and stabilized by the restoring force F_s. Designating the deviation of the center line C—C of the carriage from datum line X—X as P, the motion of the carriage is expressed by the equation

$$F_s + k_2 \frac{dP}{dT} = -F_x \qquad [32]$$

The term $k_2(dP/dT)$ is due to operation of the dashpot O which produces a force proportional to the rate of motion of the carriage.

Equation [32] of this discussion expresses also the variation in the amount of fluid or power in storage if we call F_x the rate of flow (uncontrollable); F_s the rate of flow (controllable); P the amount of fluid or power in storage; and k_2 the constant depending upon the storage capacity of the receptacle (fly-wheel effect in case of turbine, for instance).

The relationship between P and F_s can be selected at will, depending as it does, upon the characteristic of the regulator. It is quite adequate to make $F_s = k_1P$ since the resulting equation of deviation is perfectly aperiodic, that is

$$k_1P + k_2 \frac{dP}{dT} = -F_x \qquad [33]$$

This equation expresses the motion of a massless carriage M if stabilized by dashpot O and a tension-compression spring S.

If, however, we make $F_s = k_1\int PdT$, the resulting equation of deviation (after differentiation) is

$$k_1P + k_2 \frac{d^2P}{dT^2} = -F_x' \qquad [34]$$

[21] Y.M.C.A., Petersburg, Va.

where $F_x' = \frac{dF_x}{dT}$, which is another random disturbing force.

The motion represented by Equation [34] is oscillatory, since it pertains to a carriage M having a mass and stabilized only by a tension-compression spring S.

Since in some instances it is advantageous to control "to a point" and therefore to retain the term $k_1\int PdT$ in the regulator characteristic, the writer proposes in such cases the characteristic

$$F_s = k_1 \int PdT + k_3P - k_2 \frac{dP}{dT} \qquad [35]$$

When this value of F_s is substituted in Equation [32] the resulting equation of deviation P is (after differentiation) again aperiodic, or

$$k_1P + k_3 \frac{dP}{dT} = -F_x' \qquad [36]$$

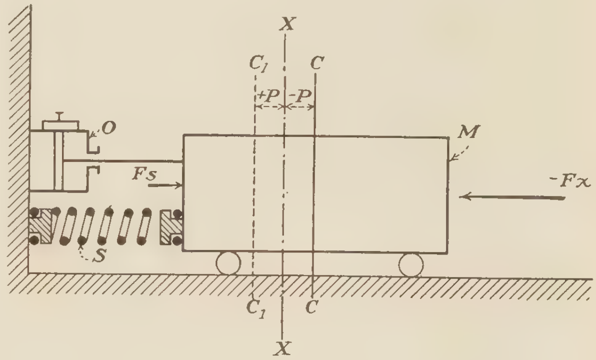

Fig. 7

An interesting additional fact is that the natural damping effect of the storage (value of k_2) can be either increased or decreased by respectively adding or subtracting the term $k_5(dP/dT)$ from the normal characteristic of the regulator. This expedient may be used to advantage in central power-station practice in order to better divide the load fluctuations between several turbines, thus minimizing the surges of current in a transmission line connecting two systems of unequal fly-wheel effect.

A different class of automatic-control problems is represented by automatic steering and stabilization. The class is represented much more literally by Fig. 7 of this discussion, since in this case we have a mass M damped by the natural damping effect O of the surrounding medium and stabilized by a natural restoring force such as of the spring S as well as by the artificial restoring force F_s, against the disturbing random force F_x.

The equation of motion of the object to be stabilized is

$$F_s \pm k_1P + k_2 \frac{dP}{dT} + k_3 \frac{d^2P}{dT^2} = -F_x \qquad [37]$$

It should be pointed out that the natural restoring force k_1P may be either negative (monorail cars) or absent (steering, of ships). The natural damping factor $k_2(dP/dT)$ is always positive, but may be absent (monorail cars). The reaction of the mass $k_3(d^2P/dT^2)$ is always present and is always positive.

The artificial restoring and stabilizing force F_s is produced by the action of a rudder or ailerons in case of steering of ships and aircraft precession of gyroscope, shifting of weights and movement of stabilizing fins in case of monorail cars and antirolling ship installations.

It is apparent that to make the motion expressed by the Equa-

tion [37] of this discussion stable and aperiodic, it is sufficient to make

$$F_s = k_4 P - k_3 \frac{d^2P}{dT^2} \qquad [38]$$

The resulting motion is expressed by an equation of the type of Equation [33] of this discussion, provided there exists a natural damping factor of sufficient magnitude.

To take care, however, of either negligible, absent, or excessive natural damping factor it is necessary to make

$$F_s = k_4 P \pm k_5 \frac{dP}{dT} - k_3 \frac{d^2P}{dT^2} \qquad [39]$$

The simplest device for obtaining the angular-acceleration term $-k_3(d^2P/dT^2)$ consists of a balance (pendulum of infinitely great radius) restrained from rotation by either a compression rheostat or by a fluid-pressure multiplier (cup-bleeder valve).

From the foregoing discussion an interesting question arises as to the proper method of automobile ride stabilization. It seems to be practical to stabilize a high-speed car by installing small stabilizing airfoil sections above each wheel, somewhat in the nature of present fenders, and to change the angle of attack of each airfoil by means of a regulator with the characteristic expressed by Equation [39]. It will be close enough for the purpose to obtain the first two terms of the Equation [39] through successive integration (electric or hydraulic) of the term $-k_3(d^2P/dT^2)$ which, of course, can be obtained easily from the inertia effect of a weight.

Another theoretically correct method of automobile ride stabilization consists of applying an artificial stabilizing force

$$F = k_1P + k_2 \frac{dP}{dT} - k_3 \frac{d^2P}{dT^2} \qquad [40]$$

(where P is the vertical displacement of car frame obtained in practice by integration of vertical acceleration d^2P/dT^2) between each corner of car frame and the axle. Such force can be generated either by a piston-cylinder or core-solenoid combination connecting frame and axle in parallel with the usual spring.

This arrangement would, of course, require an external source of hydraulic, pneumatic, or electric power for its operation, and it constitutes therefore the activated shock absorber in distinction from self-operated shock absorbers of previous designs.

A very similar and so far neglected problem is encountered in stabilization of an airplane as a whole in a vertical direction to prevent airsickness among passengers from "bumps" caused by vertical air currents. This problem can be solved by actuation of such wing-lift changing devices as flaps or slots by an automatic control responsive to the changing inertia forces acting upon a small pilot weight (U. S. Patent No. 2,015,862). Since in this case a vertical acceleration (deceleration) primarily is to be minimized, the vertical displacement being of secondary importance, a stabilizing change of lift $F = k_1 d^2P/dT^2$, equivalent to increase of plane's mass will be sufficient. However, characteristic

$$F = k_1P + k_2 \frac{dP}{dT} \pm k_3 \frac{d^2P}{dT}$$

can also be used in this case.

A problem closely related to that of automatic stabilization is presented by a radio loudspeaker, and microphone.

As before, the equation of motion of the diaphragm is

$$k_1P + k_2 \frac{dP}{dT} + k_3 \frac{d^2P}{dT^2} = -F_x \qquad [41]$$

where P = distance traversed by diaphragm, and F_x = force of electric coil or of sound wave actuating the diaphragm. Since F_x closely corresponds in shape and amplitude to original sound, it is desirable to obtain the relationship $k_1P = -F_x$.

Two methods are available to achieve this. It is possible to modify original radio impulses at the station or in the receiver to obtain the equation

$$k_1P + k_2 \frac{dP}{dT} + k_3 \frac{d^2P}{dT^2} = -F_x - k_4 \frac{dF_x}{dT} - k_5 \frac{d^2F_x}{dT^2} \qquad [42]$$

This equation is reduced by proper selection of constants k_4 and k_5 to $k_6P = -F_x$.

The second method consists of obtaining terms $-k_2(dP/dT)$ and $-k_3(d^2P/dT^2)$ from the motion of the diaphragm (by means of a small solenoid, for instance, and appropriate vacuum-tube circuit) and by impressing these terms (as a force) on the diaphragm in addition to force F_x, obtaining

$$k_1P + k_2 \frac{dP}{dT} + k_3 \frac{d^2P}{dT^2} = -F_x + k_2 \frac{dP}{dT} + k_3 \frac{d^2P}{dT^2} \qquad [43]$$

The cancellation of like terms gives us again the desired equation

$$k_1 P = -F_x \qquad [44]$$

J. C. Downing.[22] After reading Mr. Smith's paper, as well as the paper by S. D. Mitereff,[3] and the discussion[23] of the latter paper, the writer finds that we are all talking about the same subject but thinking and expressing ourselves ambiguously. Therefore, the writer agrees with the author's suggestion of having a committee sponsored by the A.S.M.E. to standardize on automatic-control terminology and classification.

Since every definition we might apply to control installations and their component parts can be stated in many different ways, some group should decide upon a terminology which will be universally accepted. The writer believes we must begin at the very beginning of the subject and arrive at the basic fundamentals and definitions before we can proceed to establish such a universal terminology. Therefore, the writer presents in this discussion his conception of what the problem is, and refers to definitions by the author which, incidentally, do not agree with those used by the writer.

Our starting point must be with the subject. Our subject can be nothing but automatic control or automatic regulation. It isn't "hand" control or "manual" control but automatic, that is, self-adjusting, or not depending on the will of man. The terms control and regulation are synonomous. This can be modified to a specific type of control by the addition of the variable controlled such as automatic temperature control or automatic level control.

We can now apply this subject of automatic control and our result is an automatic-control system. This system is a self-sustaining unit. Each part of this system relies upon the other; remove any one part and you destroy the system thereby losing the title of "automatic control." The writer can conceive of an automatic-control system which is altered to such an extent that it is still a control system but has been reduced to a different class such as a remote-control system or hand-control system.

Since we have set up an automatic-control system we can now proceed to divide it into its component parts. But, before we do that, there is one more general item to be considered and that

[22] Engineer, Automatic Combustion Control, Huntley Station, Niagara Hudson Power Corporation, Buffalo, N. Y. Mem. A.S.M.E.

[23] Discussion of paper "Principles Underlying the Rational Solution of Automatic-Control Regulators," by S. D. Mitereff, Trans. A.S.M.E., vol. 28, January, 1936, p. 55.

is the purpose or function of the control system. Naturally there must be one or more variables to be controlled within the system. These variables are factors, qualities, or conditions, the values of which must be maintained within some predetermined limits by the automatic control. Since we bring in one or more variables to be controlled we must elaborate still further on our control system to make a distinction between a system with one variable and a system with two or more variables. We can class a system having one variable as a single-element automatic-control system, and one with two variables a double-element automatic-control system. This subdivision is necessary as we might speak of an automatic level control which is a single-element, a double-element, or a triple-element class, i.e., one considering the level only, the level and flow, and the level and two flows, respectively.

Getting back to the segregation of the automatic-control system, there are three major parts: (1) The variable detector, (2) the controlling means, (3) the controller.

Part (1) has been referred to as the measuring device, impulse-receiving element, and variable responsive meter by various writers. Part (1) is the heart of the control, it is the master and the writer believes a term such as "variable detector" is a good general title. The writer cannot agree with the use of the term "meter" as his conception of the word is "to measure." All instruments are in a true sense meters but the writer's classification has been such that a meter is that type of instrument which integrates, records, or indicates the flow of fluid. The writer will grant that a meter may be used as a detector, but so may a temperature-recording element, or a pressure-recording element. The term "meter" is not general enough and is misleading. The author refers to a float and reservoir as a meter which, in the writer's opinion, should be referred to as a pressure- or level-indicating element.

Part (2) can be expressed in various other ways as long as it is known that it is the connecting method between the detector and the controller.

Part (3) is the controller or regulator which is the device used to control the variable.

Again, the author uses the term "automatic regulator," where the writer would use "automatic control system," and in using the term the author refers to the hunting of the automatic regulator, but apparently means to say the hunting action of the variable as produced by the automatic-control system. The writer does not believe that you can take any one part of the system and refer to its classification or characteristic without considering the whole system. Instead of referring to classes of regulators, the writer would speak of classes of control systems.

The writer is of the opinion that it would be well to include a definition of the value of the variable which the control system is set to maintain. This has been referred to as the "set value" and the "control point" in the author's definitions of "reset" and "damping decrement," respectively.

C. O. Fairchild.[24] Process engineers will undoubtedly welcome the author's implied proposal that the A.S.M.E. should sponsor the development of this subject and plan the preparation of compact treatises for the use of those not familiar with it. This paper is an admirable beginning. It is certainly the most successful effort to date, to classify automatic regulators, and develop terminology. The writer disagrees with the author at many points but most of these cannot be cleared up unless the subject breaks into print with full force and the sustained support of an active group.

It is quite natural that a mechanical engineer and a physicist acting in different fields should disagree, not only on the use of terms, but in the method of approaching the subject. A reasonably concise discussion of these different points of view would require another paper as long as the author's but the writer would like to give a few examples, with the purpose of cautioning mechanical engineers against drawing too many general conclusions from hydraulic or mechanical examples, and against the habit of depending too much upon a mechanical setup instead of upon a physical principle. Sir James Jeans, in the preface to his "Theoretical Mechanics" writes " . . . I believe that all students of mechanics, no matter what their aims and intentions may be, will be in the same position in one respect, namely, that they will best begin the study of the subject by trying to acquire a firm grasp of the physical principles, leaving aside at first all mathematical developments and all practical applications, except in so far as these contribute to the elucidation of the fundamental principles."

The question is raised: Which is the better method of approach to this subject, the elucidation of the fundamental principles, or the classification of types of instruments and study of their characteristics? Another possible method is to classify according to the type of application or the kind of variable to be controlled. For example, the study of level control teaches only part of the subject of temperature control, in which the principal complication is the attenuation of temperature between the controller and meter, when heat is conveyed by solid conduction. In fact, temperature control is sometimes sufficiently involved that the study of one case becomes very tedious. Nevertheless, many fundamental principles can be recognized as generally applicable.

In one sense it is not proper to use level control as typical. It is a special case of indirect control in which, in the absence of meter response lag or pure time lag, there is always a phase difference of 90 deg between the controller and meter. Thus, capacity lag alone cannot produce hunting. Physically this is identical with an electrical circuit having capacity but no inductance; one in which oscillation cannot persist. Of course, the author's use of level control is legitimate, other sources of lag being always included. In such cases it should be pointed out that during relatively slow oscillations or hunting, the phase difference is almost exactly 180 deg.

The writer does not fully agree with the author's handling of "follow-up," "reset means," and "storage-lag pacer," and the extensive use of Class VII regulator as typical. We would add a class similar to VI in which the piston and cylinder of the dashpot are connected with a spring, and make VII a subclass. We would also differentiate between true automatic reset and pseudo-reset of this added class, for which many manufacturers claim reset. We are not concerned here with the use of "reset" as a term, but with the theoretical treatment of "resetting."

The writer prefers the term "constrained" in place of "corresponding" for reasons requiring some discussion.

The writer wishes to emphasize his opinion that the author's expressed purpose deserves the hearty support of the Society without particular attention to technical criticism of the paper under discussion.

John I. Yellott.[25] The rapid increase in recent years in the number of types of controllers has unfortunately not been accompanied by a corresponding increase in the amount of literature available. Consequently, the mastery of this art is difficult for those who have not grown up with it.

The writer is of the opinion that a treatment of the subject, sponsored by the A.S.M.E. in a manner similar to the fluid-meter reports, would be of great value. Publication of such

[24] Director of Research, C. J. Tagliabue Manufacturing Company, Brooklyn, N. Y.

[25] Assistant Professor of Mechanical Engineering, Stevens Institute of Technology, Hoboken, N. J. Jun. A.S.M.E.

reports would perform the double function of standardizing the terminology of the art, and of supplying an authoritative reference to those who seek entrance to this very interesting field.

Although Mr. Smith specifically disclaims any desire to offer for universal adoption the terminology used in the paper, nevertheless it seems likely that the terms which he has used will stick. It seems proper, therefore, to question a few of them.

The expression "throttling range" is open to the objection that, for most engineers, "throttling" has a specific meaning which does not coincide with the sense in which it is used in this expression. Would not "operating range" or perhaps "functioning range" be better in that they would not be as liable to misinterpretation?

The term "speed of controlling" is also subject to criticism in that "speed" should have the length and time as dimensions. May not "speed" be replaced by some word, such as "period," which refers only to time? Where ambiguity is possible, is it not preferable to coin a new expression? It is certainly better to be entirely ignorant of the meaning of an expression than to have half an idea which is probably wrong.

Mr. Smith should be congratulated on the presentation of such an instructive paper. It is to be hoped that this will be the forerunner of a number of contributions on this important subject.

J. L. Kimball.[26] The follow-up system of compensation in regulators of the class discussed in the paper has for the last few years, gradually lost favor for two reasons. First, it results in a comparatively wide operating range, and second, it does not anticipate time lag.

It is generally conceded that time lag is the main cause of objectionable oscillations known in the art as "hunting," and while the follow-up arrangement is effective in preventing an overtravel it is not so effective in preventing a reversal of operation when marked time lag is present. The more advanced thought is to dissipate the follow-up effect in time with the dissipation of the time lag accomplished by means of a self-restoring dashpot arrangement such as shown in Fig. 1 of the paper.

The conventional follow-up such as shown in Fig. 10 of the paper results in a wide operating range due to gradient effect of diaphragm and springs meaning low pressure on high volume demand which is obviously the wrong way around as what is needed is an increase in pressure on increase in volume to compensate for increased pipe-line losses.

There are some makes of regulators on the market in which the operation of the servo motor automatically changes the pressure setting of the pressure-responsive device. But this is manifestly wrong adjustment and results, because of time lag, in two forces acting on the pressure-responsive device in the same direction and tending to an unstable operation.

For example assuming an upward movement of a plunger to close off a steam valve because the reduced pressure was slightly too high, and to prevent the plunger from overtraveling we automatically slide a weight out on the pressure beam, or tighten a spring under the beam. Now by this upward movement of the plunger and the slight closing of the steam valve, we are soon to have a reduction of pressure, but we had already increased the pressure setting of the regulator, so the loss in pressure and the increase in pressure setting are forces acting in the same direction and result in unstable operation.

The writer has been quite successful in his experiments in changing the pressure setting in the exact opposite direction to this, namely, in the same direction as the initial movement, thus anticipating time lag; at the same time stabilizing the regulator by means of the self-restoring dashpot arrangement as shown in Fig. 1 of the paper. The writer usually refers to this method as the "self-centering-self restoring" principle, as it results in stable operation at zero range.

[26] Mechanical Engineer, Ruggles-Klingemann Manufacturing Company, Salem, Mass. Mem. A.S.M.E.

W. A. Carter.[27] This paper should be welcomed by both the manufacturers and the users of automatic regulators inasmuch as it sets forth so comprehensively the principles involved in their design and use. It is hoped that the Society will form a committee of interested engineers to cover the subject more completely, as the author suggests.

The only detailed comments that the writer has to offer are: (1) In addition to regulators for the control of flow rate, level, pressure, temperature, and speed, it probably will be necessary to cover certain combinations of these. (2) Besides motive powers such as mechanical, hydraulic, electrical, and thermal, as mentioned it might be desirable to include a pneumatic class in order to distinguish between expansible and nonexpansible fluids.

R. P. Lowe.[28] From the sales-engineering standpoint, the writer believes that it is desirable at this time to encourage the establishment of a committee for standardizing the terminology and symbols for industrial instruments and regulators. The writer has attended several A.P.I. meetings, at one of which the use of certain industrial instruments was discussed by two manufacturers' representatives for the benefit of engineers and attendants. The terms used by these speakers differed to such an extent that, although the problem under discussion dealt with the simple control of level, the audience was confused. Furthermore, the ensuing argument between the speakers indicated that they evidently misunderstood each other.

The writer has spent over ten years in the design and construction of engineering works, which industry, in contrast to the manufacturing of controllers or regulators, has standardized its terminology and symbols so that one engineer can readily read the plans and understand the calculations and language of any other engineer in this field.

Engineering development in any field is hampered unless there can be a meeting of the minds of all concerned in that development. We know from experience that it takes the collaboration of a large number of individuals in any field to produce advances similar to those made by the radio, motion-picture and automobile industries. The uniformity of the drawings, which the author has used to illustrate various control characteristics, makes their differences comparatively easy to recognize. These graphic illustrations of operation serve as a shorthand means of visualizing the action of the various parts under operating conditions. It is believed that still further work along the line of illustration would aid those whose daily problem is the design, selection, and maintenance of such apparatus.

Although Mr. Smith has stated that his paper is of an elementary nature, the writer believes that it is introductory to more involved papers such as those of Mitereff.[3]

The writer particularly appreciates Mr. Smith's efforts to simplify a subject which has, until now, been generally presented in more complex and perplexing forms. The paper is, apparently, open minded and intended to invite discussion which will help to bridge the gap which at present exists between the designing engineer, sales engineer, and operator. The writer knows, from his association with the author, that Mr. Smith has incidentally used one terminology in his paper without seeking its adoption; instead, he seeks only to assist in starting an A.S.M.E. program

[27] Technical Engineer of Power Plants, Detroit Edison Company, Detroit, Mich. Mem. A.S.M.E.

[28] Sales Engineer, Builders Iron Foundry, Providence, R. I.

that will be useful to those interested in industrial instruments, including regulators.

Victor Wichum.[29] The author, in presenting the result of his analysis of the theory and application of automatic regulators, has performed a most useful service. His paper should be the forerunner of many others to follow, if industry is to get any appreciable value out of the latest developments of the instrument manufacturer.

The process engineer knows his apparatus and its characteristics and in selecting the proper type of control equipment, he is interested in knowing how "apparatus lag," for example, will affect the functioning of the temperature controller. Will it be necessary to purchase a controller with a special feature incorporated, in order to eliminate hunting, drifting, and resetting?

T. R. Olive, associate editor of *Chemical and Metallurgical Engineering* and secretary A.S.M.E. Process Industries Division, has clarified the importance of instrumentation in the process industries to his readers. He emphasizes that the great progress of these industries has been made possible through the successful cooperation of the process engineer with his knowledge of the chemical and physical principles of the plant process and the instrument manufacturer with his correct design of equipment for automatic control.

Messrs. Olive and Béhar[11] have classified industrial instruments and described and illustrated the many types available. They have made a worth-while contribution to the subject of instrumentation. The engineer in the process industry has been provided with a good foundation upon which to build his structure. He has his unit operations, his unit processes, and his flow sheets of process industries.

He should be taken several steps further. He should have access to a reliable source of information for choosing the particular type of controller which will serve his particular apparatus. For example, in the petroleum industry, should the top tower temperature controller be of the potentiometer type with a motorized valve or should it be a recorder controller with a fully compensated mercury-tube system and actuate a diaphragm valve with compressed air? What are the advantages of each type? All the large manufacturers of industrial instruments can furnish both types. The choice should rest with the user. There are process engineers who could make a recommendation based on experience. Why should not this information be disseminated? These engineers have offered to serve on an instrument committee which would make available this most valuable analysis of instrument application.

The large number of members of the A.S.M.E. who, in a recent survey, have shown their interest in the Process Industries Division, strongly indicates the desire for an industrial instrument committee. Since the process industries are so definitely "instrument-minded," why should not this second largest group in the A.S.M.E. enjoy the benefits to be derived from the continuation of this work?

H. A. Rolnick.[30] So few papers have appeared on automatic control that a great deal of confusion in nomenclature and ideas has resulted. This paper written from both the theoretical and practical points of view should help in stimulating discussion which will clarify the automatic-control problem.

L. M. K. Boelter.[31] The writer calls to the author's attention references which may be of value to the subject under discussion. These references books are by Wünsch and Rühle,[32] and Wünsch.[20]

Author's Closure

In preparing this closure, the author does not find time enough available to enable him to do justice to the extensive discussion of his paper, particularly for the digesting of the foreign references. He wishes to thank those who contributed written discussion and also those who attended the Semi-Annual Meeting of the A.S.M.E. at Dallas, Texas, where the paper was read, for their support of further activity on this subject by an interested group. Such a group met informally at the Annual Meeting held in New York last December and, after expressing their immediate interest in terminology, agreed upon the desirability of continuing as a subcommittee of the Process Industries Division and of holding a conference at the coming Semi-Annual Meeting of the A.S.M.E. to be held in Detroit, Mich. In the meantime, further papers on this subject and further remarks on terminology are invited for consideration at this meeting.

Some of the discussers apparently disregarded the intended scope of the paper: A tentative and incomplete "layout" to encourage an A.S.M.E. group to agree upon an authoritative and more nearly complete report, possibly along the general lines of the present paper. It seems desirable that such a report, following the example of those prepared by the A.S.M.E. Fluid Meters Research Committee, include material under three parts: (I) Instruments and regulators, per se; (II) regulator systems; and (III) factors affecting the selection and installation of one class or another of regulators for a given purpose, or process.

On the whole, the author restricted the material in his paper to part I, although agreeing on the necessity for parts II and III for a complete treatment; part III being particularly desired by members of the Process Industries Division, as indicated in the discussion by Chairman Wichum who sponsored the present paper.

The author agrees with his discussers that the material in part II is required for a general statement of the theory of regulation and submits that the discussions of Smith and Zucrow have partially supplied this complemental material. The author defends the restricted scope of the present paper as effectively highlighting the regulator elements and their definitions as a preliminary step for the understanding of complete regulated systems in part II. This was necessary for the introduction to this art of any one unfamiliar with regulators, and to facilitate the understanding of subsequent and more advanced papers.

Such a paper is an important work on turbine regulation[33] which follows the same general method used in the author's paper, that is, analyzing the mechanical system to establish the pertinent differential equations and determining, from their solutions, the stability of the system with given regulator and system constants. It is apparent that the teachings of this paper in a field other than that of industrial regulation, should be readily applicable to this latter field. For this end, it is desirable to have a common terminology throughout the various fields of regulation, which terminology can be attained only by adherence, in technical publications, to the use of good English and the sacrifice therein of vernacular expressions (trade jargon) peculiar to the various fields.

Taking the discussions in the order, as far as conveniently possible, of publication, McMahon's discussion, like the author's

discussion[34] of Mitereff's paper, begins by recognizing the difficulties of transition from an art to a science. Most other points that McMahon brings up as new are to be found in the present paper. He is mistaken when he states that the paper lists four desirable qualities of an automatic regulator. Actually the paper states merely that the four points are pertinent, thus avoiding any figure of merit in its presentation. McMahon is unjustified in questioning the consistency of the author's use of "sensitivity" in the paper; it has been used throughout as defined conversely by the "insensitivity" (or "dead zone"). Also, it was intended that exponent α clearly define the stability, the equations being solved either for the controlled variable or the controlling means.

It is hoped that this paper will assist in organizing those interested in this subject to permit united progress. Of course, points remain that require settling by group discussion. The author suggests that the committee encourage papers to openly present differing views and, following them, to sanction the publication of an A.S.M.E. report containing material agreed upon by the committee.

Without attempting to answer G. W. Smith's discussion in detail, it seems to the author that much of this falls under his proposed part II, especially the material on self-regulation. Although material of similar scope had been prepared by the author and E. R. Loud[35] working together, the author deleted it to restrict this paper more nearly to part I, i.e., introductory material for regulators per se. The Smith discussion helpfully refers to the work of Stein.[5] It may be remarked pertinently here that generally it is desirable to be acquainted with more than one source. The author urges that Smith, working with discussers Spitzglass and Zucrow, rewrite portions of their present discussions as a paper laying a basis for discussion leading toward part II, that is theory of regulated systems. These men can do an excellent job of bridging the present lingual gap in this art, as they show a fortunate combination of facilities in German, higher mathematics, and regulation.

It might be assumed from the discussions of Smith and Mitereff that the practical solution of an actual regulation problem is completed as soon as a differential equation has been set up. That this is not a fair assumption may appear from the Fairchild[24] quotation from Jeans, as well as from the following quotation from Trinks:

"Creative practice pays no attention to these equations, because they are too complicated. It takes much longer to master and apply them than it takes to build a governor and try it. Besides, the practically important features can be ascertained much more easily from the limiting case. (Steady hunting.) In spite of this condition, no apology is offered for the introduction of this brief sketch of the theory, because no one can ever appreciate the great usefulness of the simple equations of the limiting case unless he has wrestled for days, or even for weeks, with the solution of the complete equation. In the advanced volume a few examples of the complete calculation will be given for the benefit of those who wish to make the governing of prime movers a life study."

The tone of the Smith discussion makes it necessary for the author to point out that the paper as finally printed contained only one actual error or mistake. This was the omission, in Fig. 17 for the Class XII regulator, of the pilot valve called for by its context. Other and particular points raised by the Smith discussion are answered as follows: (1) As to self-regulation, it is commercially satisfactory to so design industrial regulators that the control valve carries the full burden of controlling resistance without benefit of self-regulation since any actual installation will generally have the benefit of some self-regulation in its system. (2) The context for Classes III and IV seems to the author to make unnecessary the corresponding portion of this discussion. The curves showing the valve travel for such regulators are proper with piston-type pilots with gradually closing ports as the control point is approached. It is also true that these curves tend to become saw-toothed in shape with electrically operated switches in place of these pilot valves. Reconsideration of the author's equations with these points in mind will show that they are correct, but that the curves may well be revised so as to appear more nearly saw-toothed in shape. These curves were stated in their introductory context as being cursory. (3) While regulation may seem very confusing from a purely mathematical viewpoint, in this connection refer to the clear physical analysis of Classes III, IV, V, VI, VII, and XII in the Spitzglass discussion. For instance, one questions that the devices shown in Fig. 3 of the paper and Class IV have equations with corresponding terms differing only in constants and not in order, since it has been established in practice that the regulator of Fig. 3 will stably control flow subject to much livelier disturbances than will the Class IV regulator. (4) As to the effect of regulator friction on hunting and the dead zone, evidently Mr. Smith has failed to consider adequately the work of Ivanoff[36] and also the common experience of those who have prevented the hammering of a water-closet valve by simply adding enough friction to absorb the kinetic energy of the unitary float valve and connecting lever arm (and the inertia effect of the water in the supply to the valve). In conclusion, none of the foregoing remarks are to be construed as minimizing the considerable value of the Smith discussion.

Grebe's discussion presents an extension of the author's classification, and attempts to apply a quantitative value to each of the classes, a matter that the author cannot comment upon inasmuch as it is one which would require open discussion. It also includes a revision of the author's Fig. 17 for a Class XII regulator that agrees with the text, the author's intent and his original sketch, which was departed from in the final preparation in an effort to improve the form but without adequate checking. It may be noted that this is a classical error, see the work of Hodgson and Robinson[37] in which in Fig. 14, page 37 the relay valve works the wrong way. This reference gives an otherwise clear treatment of regulators commonly used in steam power plants.

The Spitzglass discussion emphasizes the principal difference between the various classes of regulators in practice, that is, the speed with which they can stably operate their control valves. It should be brought out here that a Class XII regulator can compensate for lag in the regulator itself sooner, and hence better than can a Class VII regulator. However, a regulator having its meter divided as in the Class XII regulator but otherwise as in Class VII would not seem to the author to produce any unanticipated results in the present advanced state of the art.

As earlier noted, Zucrow's discussion presents complemental material in part. Zucrow's Equations [24] to [31], inclusive, seem to the author to duplicate his treatment substantially except that they are for steam instead of water, and are based on the

[34] Discussion by Ed S. Smith, Jr., of "Principles Underlying the Rational Solution of Automatic-Control Problems," by S. D. Mitereff, Trans. A.S.M.E., vol. 58, January, 1936, p. 57.

[35] Engineering Department, Builders Iron Foundry, Providence, R. I. The author is now hydraulic engineer with the C. J. Tagliabue Manufacturing Co., Brooklyn, N. Y.

[37] "The Development of Automatic Combustion Control Systems for Industrial and Power Station Boilers," by J. L. Hodgson and L. L. Robinson, Proceedings of the Institution of Mechanical Engineers, vol. 126, 1934, pp. 59–169.

half cycle instead of the complete cycle of oscillation. However, Zucrow's Equations [31*a*], [31*b*], and [31*c*], and Fig. 6 of this discussion are noteworthy, although stated to be based on the work of Wünsch.[20] Actually it must be remembered that all of these equations neglect the water-hammer effects which occur when a control valve is moved rapidly, i.e., the momentary increase in velocity-pressure resulting from the destruction of the momentum of the fluid in a pipe while the control valve is being closed producing a momentarily increased velocity therethrough.[38]

Mitereff's remarks are stimulating and on the purely mathematical side. At the same time, it seems to the author that Mitereff's mathematical generalization based on Fig. 7 of this discussion, does not aid in the visualization of typical industrial regulators. Indeed, any such mathematical abstractions become dangerous when they become so far divorced from reality as to hinder the offhand recognition of equivalents, and thus deprive the engineer and inventor of the benefit of the check of his instinctive qualitative judgments based upon his practical experience with such devices. Offhand, Mitereff's device shown in Fig. 7 of this discussion does not seem to represent the several sources of damping and lag noted by Smith, Zucrow, and the author. As to the problem of turbine regulation, the closure's first reference[33] shows the present state of the art for steam turbines while other references[39,40] show the state of the water-turbine regulation art to be more advanced in 1930 than indicated by the context of Mitereff's Equation [36].

The simple electrical analogy used by Fairchild is correct as far as it applies, which is only to "corresponding" regulators. It states broadly that with level regulation having capacity lag, there is a lag of 90 deg between controller and meter, which capacity lag cannot produce hunting in the absence of meter response lag. This raises the point that valve speed is relatively important. Consider any "noncorresponding" regulator for a given capacity lag in which the pilot supply and consequently the control-valve speed has gradually been increased until the stability is small. A further large increase of capacity lag will permit the valve to overtravel its proper control position long before the level has changed appreciably. With a reservoir of infinite size, it is apparent that any finite valve speed and any finite stiffness of reset spring (in Class VII) will cause the valve to have unstable two-position regulation, even without the introduction of any metering lag. In other words, the stability is related to the capacity of the reservoir as well as to the reset spring stiffness and valve speed. Fairchild, Smith, and Stewart[41] mentioned another lag frequently met with in temperature regulation. This lag is the delay in transporting a heating medium from the controlling to the metering point which lag produces a phase angle depending upon the distance transported; in extreme cases the lag can be so great as to produce an apparently leading phase angle in a steadily hunting system.

The Downing discussion offers "variable detector" as a substitute for "meter" in the author's paper. "Senser" and "responder," respectively for "variable sensitive means" and "variable responsive means," are the only substitutes for "meter" that the author personally would consider acceptable. However, the Downing offering will receive consideration by the group. The Downing discussion presents an interesting side light on classification according to the number of variables, besides demonstrating the practical necessity for reaching agreement on terminology.

Yellott's discussion raises the point as to controller "speed," an important and convenient term that is commonly understood as the percentage of full controller travel per unit of time, a value immediately obtainable from the length of time required for the controller to move through its full travel. This use of "speed" seems preferable to introducing another "period" in a system where there already are two time durations: the period T of a complete hunting cycle and the interval t_i required for the amplitude of the hunting oscillations to drop to 10 per cent of their value at the start thereof.

Apparently Kimball's "self-centering and self-restoring" principle is that described in the paper under the Class XII regulator; see Fig. 17 of the paper as corrected in Fig. 3 of the Grebe discussion.

The author particularly welcomes Carter's suggestion for increasing the value of the proposed report to the important field of regulators used in power stations.

The Lowe discussion expresses encouragement and appreciation of efforts to standardize the terminology and simplify the presentation of the theory and practice of regulation. Such ideas must be shared by firms, such as he is associated with, to make possible effective work on this program. The author is glad to have this opportunity of thanking Chairman Wichum for his consistent interest in and support of this work of an educational nature, Rolnick for his helpful comments from his detached viewpoint, and Boelter, whose friendly interest over a period of years is likewise appreciated by the author. Professor Boelter in a further communication has furnished an interesting reference[42] for a bibliography on the subject under discussion.

In conclusion, this subject is of present and increasing importance to industry and engineers therein. The author urges all concerned to cooperate actively in forwarding a program that will at least reduce the present "lag" between the progress of industrial regulators and their technical literature. Unfortunately most of the burden of this work must necessarily fall upon the more numerous users since the limited technical staffs of the much fewer regulator manufacturers are generally unavailable or without adequate stenographic assistance for this task. After all, these reports are intended for the use of the industrial engineers and their associated staffs rather than for the purpose of reference for designers of regulators. However, the active cooperation of both groups is essential and to their mutual interest.

The Accuracy of the Cleanliness-Factor Measurement for Surface Condensers[1]

Joseph Gershberg.[2] The proper criterion for the accuracy of sampling with old test tubes is the agreement between the average heat transmittance of these tubes and that of the entire condenser. Comparison of values of U given in Table 1 of the paper shows that the average heat transmittance for four loads on each day of test as determined by old test tubes differs from

[1] Published as paper FSP-58-5, by P. H. Hardie and W. S. Cooper, in the July, 1936, issue of the A.S.M.E. Transactions.

[2] Chief Testing Engineer, The New York Edison Company, Inc., New York, N. Y. Mem. A.S.M.E.

the similar average for the entire condenser by —0.4 per cent on the first day (runs 1 to 4), —5.3 per cent on the second day, +1.0 per cent on the third day, and —2.0 per cent on the fourth day. Correction for average fouling does not alter these differences appreciably. Average cleanliness factors computed on the basis of a correct constant overall value of U_n, which would obtain if an adequate number of new sampling tubes were employed, therefore, will indicate the same disparity between a sample of old tubes recommended by the authors and the entire condenser as in the case of heat transmittances. Inadequacy of six new tubes in a sample of 24 tubes to represent correctly the entire condenser can be readily recognized from the study of values of U_n computed from the data in Table 1 of the paper. Comparison of average U_n for a 24-tube sample with that for a 96-tube sample shows a difference of +0.1 per cent for runs on the first day, —2.2 per cent on the second day, +4.0 per cent on the third day, and —2.0 per cent on the fourth day. It is to be noted that U_n is practically the same on the second and fourth days, which fact definitely indicates that the error in cleanliness factor due to a 24-tube sample on those days is —5.3 per cent and —2.0 per cent, respectively. Yet according to authors' method of comparison these errors are —1.8 per cent and + 1.8 per cent. The discrepancy is obviously masked by deviations of heat transmittances from a true value in both new and old tubes of 24-tube samples.

The authors' tests show quite conclusively the futility of obtaining assured accuracy of sampling with old tubes. Why such a sample after all? It is not justified, since the value of the bulk can be readily determined. Would it not be better to measure the heat transmittance of the entire condenser and to establish a fairly accurate value of U_n by use of an adequate number of new tubes judiciously distributed throughout the condenser? It seems a greater accuracy in the measurement of cleanliness factor will be thus obtained, perhaps at less cost.

J. F. Grace.[3] The authors determined, as shown in Table 2 of the paper, that the average cleanliness factor for the 96 tubes was 0.509 and that the average heat transmittance U_n of new tubes was 596 Btu. For the sample tubes in the front-line groups such as N, P, R, and S near the steam entrance to the condenser, the authors' Table 2 shows for group N that $CF = 0.478$ and $U_n = 715$ Btu, for group P that $CF = 0.478$ and $U_n = 694$ Btu, for group R that $CF = 0.486$ and $U_n = 737$ Btu, and for group S that $CF = 0.456$ and $U_n = 677$ Btu. These values show that the heat transmittance of these groups is above the average of the 24 clean sample tubes and that the cleanliness factors of the adjoining foul sample tubes are below the reported average cleanliness. In such groups as Q, W, and T, adjoining the front-line groups, the authors' Table 2 shows for group Q that $CF = 0.536$ and $U_n = 592$ Btu, for group W that $CF = 0.525$ and $U_n = 532$, and group T that $CF = 0.575$ and $U_n = 480$. The heat transmittances of these groups are below the average of the 24 clean sample tubes while the cleanliness factors are above the average.

These values coincide with those given by Seider[4] and by Tinker[5] which indicate that the same thickness of film which reduces transmittance 17 per cent below a clean-surface performance of 500 Btu will reduce transmittance 25 per cent below a clean-surface performance of 800 Btu shown by a high heat-transfer tube closer to the steam entrance or favored by higher water velocity.

Therefore, if front-line sample groups in locations where tubes are widely spaced, such as groups N, P, R, and S in the authors' Fig. 1, represent less than average condensation per sample group and also reduce the cleanliness factor calculated for the entire condenser, they are largely, if not entirely, responsible for the bend in the diagonal line plotted in Fig. 4 of the paper. This effect is to the advantage of the manufacturer and to the disadvantage of the owner.

Choice of location or weighting to represent equal weight of condensation per sample group may thus prove of greater importance than the number of groups of sample tubes.

Paul Bancel.[6] It is noted that runs 9 to 12, inclusive, in the authors' Table 1 give results of condenser performance about the middle of the four-day test period. The cleanliness factors obtained during these runs agree closely with the results for mean cleanliness conditions given in Table 2 of the paper. It is observed from the authors' Table 2 that runs 9 to 12, inclusive, include tests of isolated groups of top tubes N and R and that the heat transmittances of these groups are the highest isolated values attained under the prevailing cleanliness.

If all the tubes in the condenser could have been top tubes, which is an ideal condition of 100 per cent tube-nest efficiency, they would have worked at the transmittance rates of groups N and R, or approximately 350 Btu. Table 1 of this discussion shows that the actual performance during the maximum-load run No. 12 was 87.5 per cent of the performance of groups N and R. This is the apparent tube-nest efficiency and is analogous to the Rankine cycle efficiency of a turbine. The average for all loads, as noted in Table 1 of this discussion, was 83.5 per cent.

It is true that the average cleanliness factor for groups N and R is 0.482 whereas it is 0.504 for the entire condenser during runs 9, 10, 11, and 12, because the lower tubes are progressively cleaner. This is an advantage of the particular design. The tube-nest efficiency referred to top tubes under the existing conditions profits by reason of the design and is correspondingly higher than it would be with clean tubes.

TABLE 1 TEST PERFORMANCE OF TUBES DURING RUNS 9 TO 12

Run no.	Load 10^6 Btu	Observed CF	U	CF from Table 2[a]	U_c	U_o for groups N and R	U_c/U_o per cent
11	559	0.50	275	0.509	280	345	81.0
10	690	0.50	284	0.511	290	349	83.0

[a] Values taken from Table 2 of the paper.
CF = cleanliness factor.
U = overall condenser heat transmittance, Btu per hr per sq ft per deg F log mean-temperature difference.
U_c = overall condenser heat transmittance corrected.
U_o = heat transmittance for old tubes.

H. G. Hiebeler.[7] The authors have in this, and in their previous paper,[8] made important contributions to the art of measurements of performance of steam-condensing units. The last three condensers at the Deepwater (Houston) station have been the subject of check for the comparison of performance with manufacturers' guarantees. The testing methods were substantially

those developed at Brooklyn and described by the authors in their previous paper.

It hardly seems necessary, in view of the thorough manner in which the Brooklyn Edison data have been prepared and analyzed, to review the similar data from the Deepwater tests and the writer will confine himself to commenting on the results obtaining on the tests of the last condenser, a 35,000-sq ft single-pass unit, having 6370 tubes, $^7/_8$ in. OD, no 18 Bwg, 24 ft long, serving a 35,000 kw turbine. Two two-speed circulating pumps having a combined total delivery of 63,000 and 87,000 gpm, respectively on low and high speeds were installed.

A series of 42 tests were run of an average duration of 50 minutes each with readings recorded simultaneously at five-minute intervals. Data were taken with machine loading corresponding to approximately one-half, three-fourths, and full-rated machine capacity. The condensate was measured by a calibrated venturi meter and all heat-transmittance calculations were based on the absolute pressure and temperature existent near the condenser inlet throat since the guarantee specified the back pressure should be measured within 24 inches of the turbine-exhaust opening. For the temperature and pressure conditions of these tests and the design of the condenser there was apparently very low pressure drop through and around the tube bundle.

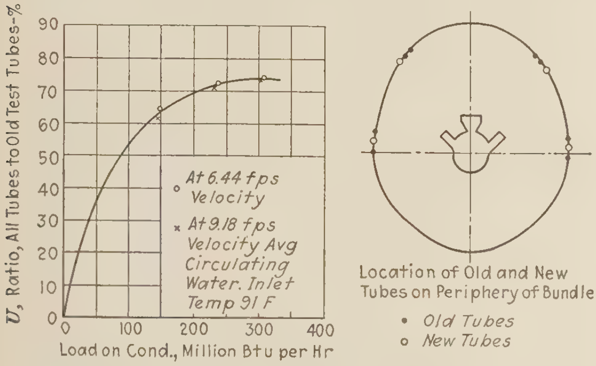

FIG. 1 RELATION OF HEAT-TRANSMITTANCE RATE OF OLD TEST TUBES ON THE PERIPHERY OF A BUNDLE TO THAT OF THE CONDENSER AS A WHOLE

The number of test tubes used in each series was twelve, comprising four groups of one clean and two dirty tubes in each of four quadrants. These tubes were selected at random adjacent to or on the periphery of the tube bank. It was felt that in such locations the tubes would receive sufficient quantity of steam to satisfy their individual capacities to condense. Such location would also probably give high temperature rise increasing the accuracy of measurement. It is believed that the cleanliness factor as found by the use of the tubes on the outside of the bundle reflects the condition throughout the test bundle within the limits of accuracy possible.

Fig. 1 of this discussion shows the relation of unit-transfer rate U of old test tubes on periphery of bundle to that of the condenser as a whole. This ratio might be considered an index or a measure of "bank efficiency" or steam penetration and seems independent of water velocity or tube cleanliness (through test range) but varies with the loading of the unit.

The writer cannot wholly agree with the authors' conclusion that less than sixteen test tubes give inaccurate or incorrect results on units of 7500 or less tubes. Small condensers do not warrant the refinement in testing possible with larger units and this factor should be considered. We check the authors' conclusion that cleanliness-factor relation to overall performance is not a straight line but the test range for our tests (53–87 per cent) was too short to draw definite conclusion as to the shape of the curve or the effect of circulating temperature variation (88–94 F) through these tests.

Considerable variation was found in the transfer rates of new tubes, a total of 28 new tubes being tested in one condenser alone. A variation in excess of 10 per cent each way from the average of 28 tests at comparable temperatures and velocities was obtained on both the high- and low-speed runs. This could not be explained on the basis of location of the tubes or other recognizable factors and raised the question as to how closely it was possible to determine condenser cleanliness until the standard against which it is measured is more definitely fixed. While agreeing with the authors that tests should be made in place in the condenser, and with circulating water from main sources which was also done in the writer's case, it is believed that considerable work with the tube calorimeter might be done to determine how much variation in performance might be expected between "new tubes" as received from the manufacturer or taken from stock. Some new tubes were tested exactly as received, some after being flushed with gasoline or benzene to cut any grease that might be present (this at the suggestion of the condenser manufacturer) with no discernible effects in reducing the variation in heat-transfer rates between several new tubes.

It might be added that the condenser was expected to meet performance with 90 per cent tube cleanliness as referred to new tubes. The 10 per cent allowance represented design margin allowed to take care of the formation of oxide film on the outside and other factors. It was recognized that 100 per cent cleanliness would never be obtainable in service and it was assumed that 90 per cent would represent the maximum condenser cleanliness obtainable by the best possible cleaning methods under operating conditions. The 10 per cent may be thought of as representing factors common to any condenser and not attributable to local water conditions. It is interesting to note that the condenser cleanliness factor averaged about 75 per cent and varied from 53 to 87 per cent of new tubes on the same test. Several mechanical methods of cleaning were tried. Best results seemed to be obtained by rodding with wire brushes. Incidentally the variation in cleanliness factor could not be attributed to the variation in heat-transfer rates of new tubes although apparently this influenced it somewhat.

It would appear that the whole question of determining condenser performance hinges on the ability to measure with reasonable accuracy the water pumped, the steam condensed, the quality or the heat content of the steam condensed, and the absolute pressure in the condenser shell. It is believed that the measurement of water temperatures, the steam condensed, and the quantity of water flowing through the test tubes as outlined in the authors' previous article can be done very accurately. However, the measurement of the water pumped and determination of heat content of the steam to the condenser are more difficult as is the measurement of vacuum. The mercury-column gages and temperature readings indicate a wide discrepancy at several points in the condenser neck as might be expected. Final-check agreement of absolute pressures as measured by the columns and the thermometers was obtained within 0.02 in. Hg after all possible care was used to avoid impingement or eddy effects. For the vacuum conditions and steam velocities of this installation these effects are probably of small magnitude compared to those which would be secured with lower absolute pressures and higher velocities obtaining under colder-water installations.

It is felt therefore that the tests which were conducted have contributed much to the knowledge of condensers, to the maintenance of performance of such units, but one cannot feel wholly satisfied that under the present conditions or the

methods outlined the absolute performance of a unit is closely measurable. The authors are considered on the right track but refinement of testing methods and further investigation are necessary before drawing any but very general conclusions.

Authors' Closure

Mr. Gershberg, in basing his analysis entirely on the values of heat transmittance, has obviously missed an important point which was covered in the paper, namely, that the heat transmittance is affected by several variables only one of which is the cleanliness factor. He has overlooked the fact that it is impossible to know, except very roughly, what sample-tube positions will be representative of the steam conditions throughout the tube bank. By making measurements on adjacent old and new tubes the authors avoided this pitfall.

Mr. Gershberg suggests that the cleanliness factor be determined by using the overall heat transmittance for U_o, and an adequate number of new test tubes to determine U_n. Although this method appears to have some advantages the authors do not believe it could be relied upon unless a large number of new tubes were employed. The positions selected, as pointed out in the preceding paragraph, would have an effect upon the results which could not be predicted. Furthermore, by increasing the number of new tubes to be installed the cost of the test is more likely to be increased than reduced.

Mr. Grace calls attention to the fact that the choice of sample-tube locations and the method of averaging are important as well as the number of sample tubes. The authors agree with Mr. Grace, but they wish to emphasize that if the sample tubes are distributed so that all parts of the condenser are represented, considerable latitude in selecting positions is possible without adversely affecting the results. This is illustrated in the test reported since the measurements of the overall cleanliness factor, using the different groups selected for each of the four days, gave approximately the same values.

Regarding the method of averaging, the overall cleanliness factor if properly determined must not only give weight to the individual values of the fouling according to the load on each section, but must also include a position factor, since the same degree of fouling does not reduce the heat transmittance the same in all positions. Mr. Grace seems concerned about what amounts to the position factor in the method of computation proposed. He implies, by his reference to the papers by Seider[4] and by Tinker,[5] that the fouling resistance R_f, where

$$R_f = \frac{1}{U_o} - \frac{1}{U_n} \qquad [1]$$

is a better expression to use than the cleanliness factor. As can be seen from this equation the fouling resistance is computed from the same data as the cleanliness factor. Either could be used. From the test data obtained so far, the fouling resistance seems to be almost unaffected by water velocity and the tube position, but susceptible to a much greater error than the cleanliness factor if the exact steam temperature at each tube is not known.

The fouling resistance may be a better indication of the condition of an individual tube. However, since the fouling resistance for each tube must be weighed by the position factor in order to determine the overall fouling resistance, there is no advantage in its use over the cleanliness factor which already includes the position factor as well as the condition factor. The authors, therefore, cannot agree with Mr. Grace's opinion that the method of computation used accounts for the bend in the diagonal line in Fig. 4 of the paper.

Messrs. Bancel and Hiebeler discuss another valuable use that can be made of the sample-tube data. The tube-nest or tube-bank efficiency is valuable information which should be determined on all condenser tests.

Mr. Hiebeler's discussion should prove very illuminating to any one attempting to make a cleanliness-factor measurement for the first time. While it is impossible to analyze the causes of his not feeling wholly satisfied with the results obtained from the cleanliness-factor measurements, the authors would like to point out a few things which they suspect might have reduced the accuracy otherwise obtainable. First of all, to assume that tubes in any one part of the condenser are representative of the entire condenser is open to question. Even though this were true, there would still be an appreciable error because the cleanliness factor includes the position factor (discussed previously) and only the outside positions were represented. A total of 24 test tubes instead of 12 would have undoubtedly given more consistent results.

It is true that new tubes are not an absolutely uniform standard but they are the best we have to work with. As much as 10 per cent variation in new tubes has also been noted by the authors, but when as many as six new tubes were used a fair average value has been obtained. Possibly, some of the disagreement between new tubes obtained by Mr. Hiebeler was due to other causes, such as, rapid fouling between the time of installation and the beginning of the test.

Mr. Hiebeler states that the cleanliness factor of the condenser at the Deepwater (Houston) station was expected to be 0.90 after cleaning, but that the nearest to this value actually obtained for an individual tube was 0.87 after trying several methods of cleaning, and the average was 0.75. This illustrates a point which the authors have been emphasizing, namely, that even though the cleanliness-factor measurement is not perfect it is reasonably reliable and certainly far better than any guess.

Failure of Metals Due to Cavitation Under Experimental Conditions[1]

Max Kurrein.[2] The author has presented some excellent micrographs showing variation of structure as a result of mechani-

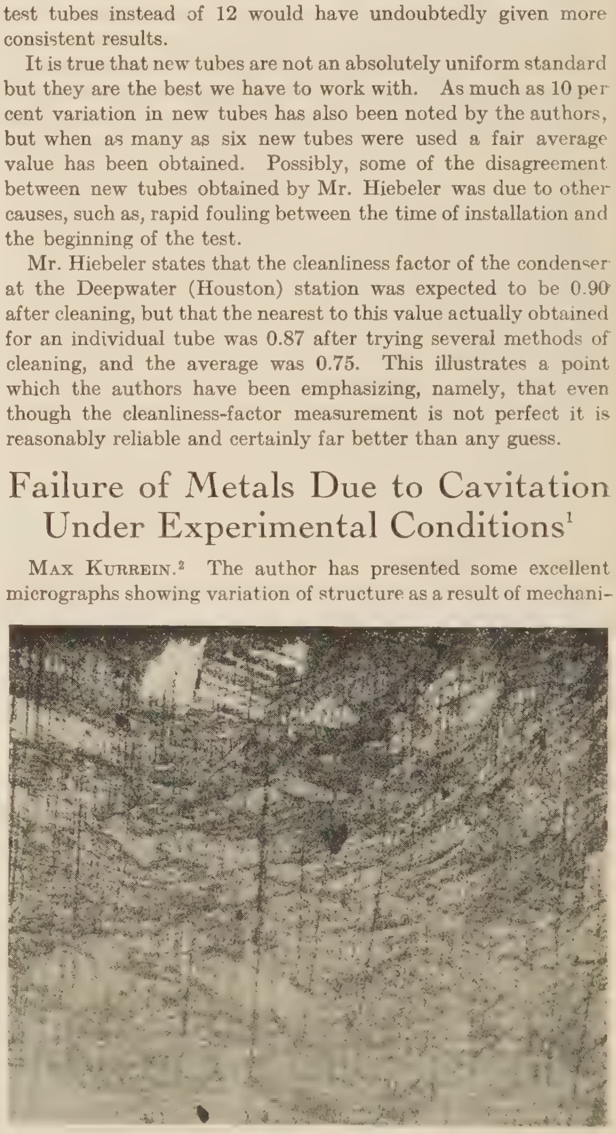

Fig. 1 Cracks in a Specimen Caused by a Punch Press Striking One Corner of the Specimen

[1] Published as paper HYD-58-1, by H. N. Boetcher, in the July, 1936, issue of the A.S.M.E. Transactions.

[2] Professor, Hebrew Technical College, Hadar Hacarmel, P.O.B. 955, Haifa, Palestine. Mem. A.S.M.E.

cal deformation due to outside forces. The author ascribes these variations to fatigue, that is, repeated impacts each of which is too small to produce the shown deformation. The writer would like to refer to Figs. 7*a* and 10 in particular. It has been known for more than 30 years that every outer deformation of a piece of work causes an adequate deformation of the microscopic structure in the grains of the material, but the writer believes that the author's Figs. 7*a* and 10 are the first examples of a similar relation due to fatigue. Assuming that the concentric deformation of the grains in Fig. 7*a* is caused by repeated impacts at one point near the middle of the upper portion of this figure, the writer would like to call the author's attention to Fig. 1 of this discussion.

Fig. 1 of this discussion, showing the same deformation as the author's Fig. 7*a*, was obtained by the writer while engaged in

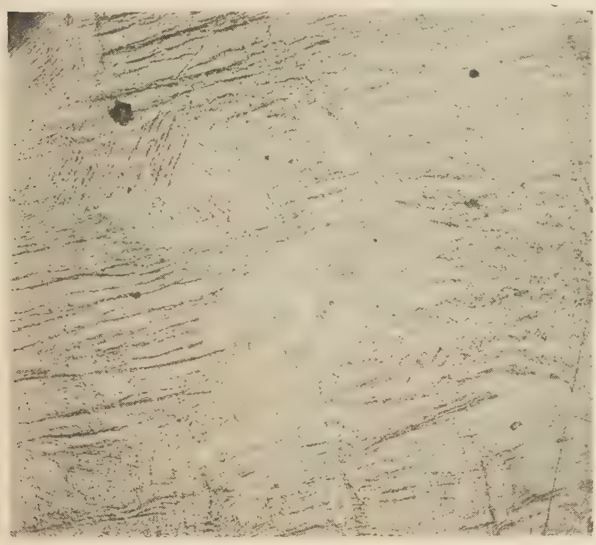

Fig. 2 Slips Bands on a Sheared Surface

research on certain punch press work. During the research study, the test piece was not parallel and was apparently struck on only one corner by the punch, thus distributing the deformation from a center.

Fig. 2 of this discussion, also obtained by the writer in the previously mentioned research, shows slip bands on a sheared surface, similar to those shown in the author's Fig. 10. As in the case of the author's tests, Fig. 2 of this discussion shows that the zone of influence penetrates on a sheared piece only a short depth from the sheared surface of the material. Beyond this depth the structure of the grains is not affected at all. Since the author's tests were made by impact and the writer's tests were made by application of a steady load, and the results of both tests showed the same characteristics, it would seem that the transmission of forces and deformation in loaded bodies must be sought in a direction heretofore not investigated.

Author's Closure

As Professor Kurrein states correctly, the deformation of the grain structure by outside forces, such as shown by his Fig. 1, is a well-known and rather commonplace condition. The appearance of slip bands under fatigue conditions is not a novel discovery either. I refer, for instance, to many excellent illustrations in H. J. Gough's book on "The Fatigue of Metals" as published in 1924.

The peculiarities of cavitation make it inadvisable to assume concentration of repeated impact stresses in any one spot as suggested by Professor Kurrein. Cavitation, especially under the accelerated conditions of the tests, exposes the affected surface to a series of blows hitting it in very much the same manner as a rain shower does the ground. Investigational work carried out after presentation of the paper at the 1935 Annual Meeting of the A.S.M.E. and intended to establish the reasons for the apparent lack of influence of corrosion resistance on cavitation fatigue showed the rain of blows to result in a kneading action with stresses exceeding the yield strength of even the strongest metals in a surface layer. This overstressed layer, though often extremely thin, absorbs the effects of corrosion and makes it possible for fatigue failures to appear and progress in the underlying metal depending entirely on mechanical properties and conditions. Further details are given in a paper by the author which appeared in *Zeitschrift, V.D.I.*, vol. 80, December 12, 1936, p. 1499.

Arc Welding Structural Alloy Steels[1]

F. T. Llewellyn.[2] Although this paper is admittedly only a progress report, it presents valuable information relative to a large and meritorious program of investigation that is being carried out by the author at the Watertown Arsenal. While many of the results will have wide application, the writer believes that the title of the paper should be qualified by some such phrase as, "especially as applied to the construction of ordnance." Otherwise there is the danger of assuming that the conclusions are directly applicable in all fields of welding.

The author recommends that a maximum limit of 0.25 per cent be set on the carbon content of weldable alloy steels. A suspicion arises that he rather expects steel makers to take issue on this point. The writer sees no reason to do so. Indeed, it is his reaction that, in some cases, the author's proposed limit may be too liberal.

The report lists 13 different grades of low-alloy high-tensile steel. Apparently the only properties on which tests have so far been completed are ultimate and yield-point values. Based on these properties alone, the author presents a comparison by the aid of which he suggests that designers may select the grade which should most satisfactorily meet their strength requirements. The author quite properly points out, however, that other factors may change the desirability of any of these steels for a given welded structure.

It is assumed that the final report will present a more comprehensive classification that takes impact resistance into consideration. The behavior of a few of the grades under tension impact is shown in the charts and doubtless, when all the tests have been completed, the author will present another classification in which all the results are included. Meanwhile, designers should recognize that the comparison is not yet complete.

In addition to the properties included in the Watertown investigation, there are frequently cases where resistance to fatigue and to corrosion become critical. These properties also should be considered in any attempt at a general ranking. In industrial applications the comparative cost per pound of the respective steels is another feature which will sometimes determine their optimum suitability in a design.

The author is to be congratulated on this progress report. His final report will be awaited with interest.

Operating Experience With Pulverized Texas Lignite in a Large Central Station[1]

H. E. Martin.[2] The author has recorded in a broad and interesting manner a development having significance from a variety of angles. The fact that Texas lignite continues to be used at the Trinidad station in competition with the oil and gas fuels that are now available at low cost, has demonstrated the feasibility of utilizing this fuel as a prime source of power generation. Texas is thus assured that its enormous lignite resources will constitute a source of cheap power regardless of the market and supply conditions in the more popular oil and gas fuels. Greater use of this fuel may be expected.

The author points to low fuel costs at the plant and desired availability of equipment as being controlling factors in the design of the plant. This has resulted in designs and arrangements of equipment that for this size of plant are unique in their simplicity, of which the single-pass boilers operated on natural draft without air heaters or economizers are examples. The simplicity of this station may be studied with profit by other designers, especially for locations where fuel is cheap.

Those interested in the extension of the use of pulverized fuel will take satisfaction in observing this large commercially successful installation using low-grade lignites as fuel. The bin system of pulverized-fuel firing is used, although since the initial installation was made in this station the direct-fired system has come into more general use, and it is to be expected that in future installations consideration will be given to this still simpler and less expensive system. The author's comments on the problems involved in such a system based on his observations would be of value.

The high moisture content to be evaporated in the furnace together with the rather large areas of bare-tube waterwalls are responsible for low furnace temperatures. It would be interesting to know the effect of hotter furnaces on performance and more especially on the superheat curve, which the author states is steeper than anticipated.

It will be noted that the boilers installed in 1931 are of the cross-drum single-pass type with converging gas pass. The boiler has a low draft loss and is ideally adapted to natural-draft operation. No capacity limitations of any kind appear to have been reached in connection with the boiler.

The designers and operators are to be congratulated on the performance of this station. If the plant were to be built today taking advantage of the latest developments, it is quite safe to predict that pulverized fuel would be retained, as would simplicity of design and moderate efficiencies. Modifications would likely be made in arrangements of equipment and of heating surfaces made available since the existing plant was built.

NOTICE TO AUTHORS on the Preparation of Manuscripts

THE most satisfactory and economical results in publishing technical papers are obtained with the most carefully prepared manuscripts. Observance of the few simple rules which follow will help to assure correctly printed papers at minimum cost.

Length: Be brief. Eliminate unnecessary words, descriptions, data, drawings, charts, illustrations, tables, mathematics. Papers requiring more than eight pages when printed are likely to be returned for condensation or rejected. Solid type runs 1200 words per page. Allow extra for the title, footnotes, bibliography, illustrations, and mathematics.

Manuscripts: Typewrite, double or triple space, on one side of standard-size paper. Leave ample margins. Cut captions, on a separate sheet, illustrations, and tables should accompany manuscript.

Bibliography: Footnotes and bibliographical references must be complete and thoroughly checked for accuracy. Do not abbreviate. Put in A.S.M.E. style: Title, author, name of periodical, volume and number, date, page. If a book: Title, author, publisher, place of publication, date, page referred to.

Mathematics: Check carefully. Write symbols clearly. Distinguish between capital and lower case letters. Mark zero to avoid confusion with letter O; numeral 1 with the letter "el" (l) or prime (′); Greek letters (alpha with a, kappa with k). Mark subscripts and exponents clearly. Avoid dots and bars over letters.

Illustrations: Good halftones are made from good photographs. Send black and white photographic prints, not blueprints or other halftones. Make drawings, graphs, and diagrams as simple as possible. Put explanatory notes in captions rather than on the graphs. Use black ink and white paper, or preferably tracing cloth. Letter in pencil; relettering in ink will be done by A.S.M.E. draftsman for uniformity of size and appearance. Check thoroughly as changes cannot be made on the cuts.

Check Everything: Delay, expense, and errors in printed papers can be avoided only by careful and repeated checking. Changes in proof are unnecessary if manuscripts are thoroughly checked and are carefully and clearly prepared.

Help the Society to do a better publishing job at less expense by observing these simple rules when you prepare a manuscript.

FOREWORD

With the bringing together in this book of the personnel of the Council and committees of the Society, the alphabetical and geographical lists of members of all grades, including the members of the Student Branches, for the past two years published in the Student Branch Bulletin, there is made available in one place for the first time since 1931, a complete "yearbook" of information of this nature. This forms Part 1 of the Society Records for 1937, which is a section of the Transactions of The American Society of Mechanical Engineers. Parts 2 and 3 will contain the memorials of deceased members and indexes to publications.

The "RI" preceding page numbers in this section is the symbol for Record and Index, and these pages, as well as the later issues of the Society Records for the year, will form part of the bound volumes of Transactions of the Society.

The use of this section will be facilitated by reference to the index on pages RI-34 and 35.

Membership List

The Membership List itself contains the names of all those who were members ot the Society on December 1, 1936. It is divided into two sections. The Alphabetical List (page 1), which gives the name and location of each member, is the key to the Geographical List (page 37), which includes the member's grade of membership, his business connection, and his mail address.

The United States, including its territories and dependencies (Alaska, Canal Zone, Hawaii, Philippine Islands, and Puerto Rico) is placed first in the geographical list. It is followed by other countries in the Western Hemisphere, Canada, Newfoundland, Mexico, Central America, the West Indies, and South America, in the order enumerated. In the Eastern Hemisphere the individual countries are listed alphabetically under the headings Africa, Asia, Europe, and Oceania. Cross references to the territories and dependencies of the United States are inserted at the proper points, and other cross references cover variations in names of countries. Facing page 1 is an index giving the number of the page on which each country will be found.

In the United States and Canada, the name of each city which falls within a Local Section is followed by the name of that Section. Members residing in cities where no Section is mentioned may affiliate with any Section, without additional dues, upon request to the headquarters of the Society.

Where more than one address is given for a member, the first is the business address and is usually followed by the address to which he desires his mail sent. In some instances a "home address" is given. This was done in cases where members desired to be grouped under city headings which are not part of the business or mail addresses.

The dates and letter symbols in parentheses after the name of a member indicate his grade of membership and year of election or promotion to each grade. The letter sym-

bols are H - Honorary; F - Fellow; A - Associate; AM - Associate Member; and J - Junior.

Where a single date is not accompanied by a letter symbol, the grade of member is to be understood. Also where several dates are given, with no letter symbol, the final date indicates the year of election to full membership.

Restrictions On Use of Membership List

This Membership List is issued for the personal use of members of The American Society of Mechanical Engineers in connection with Society and professional affairs.

Each member is expected to conserve it and not to permit his copy to be used for the basis of circularization. Such use is annoying to fellow members.

The American Society of Mechanical Engineers

THE members of the Council and of its standing and special committees given on the following pages are those in office on January 1, 1937, serving for the official year 1936–1937. The terms of office of members of other committees are not fixed by the official calendar.

R. H. McLain, *Chairman and Representative on Council* (1937)
L. R. Ford (1938)
F. C. Spencer (1939)
Norman Litchfield (1940)
H. E. Molé (1941)

Advisory Member: H. A. Lardner (1937)

PROFESSIONAL DIVISIONS

Crosby Field, *Chairman and Representative on Council* (1938)
G. B. Pegram (1937)
L. K. Sillcox (1939)
H. B. Reynolds (1940)
Victor Wichum (1941)

(*Personnel of Professional Divisions' Executive Committees, p.* RI-5)

LOCAL SECTIONS

W. R. Woolrich, *Chairman and Representative on Council* (1938)
J. N. Landis (1937)
D. B. Prentice (1939)
A. J. Kerr (1940)
H. L. Eggleston (1941)

(*Personnel of Local Sections' Executive Committees, p.* RI-10)

CONSTITUTION AND BY-LAWS

H. H. Snelling, *Chairman and Representative on Council* (1937)
W. H. Kavanaugh (1938)
R. D. Brizzolara (1939)
G. E. Hulse (1940)
S. R. Beitler (1941)

Junior Advisor: H. S. Eddy (1937)

HONORS AND AWARDS

R. C. H. Heck, *Chairman and Representative on Council* (1937)
L. P. Alford (1938)
Harte Cooke (1939)
W. H. Carrier (1940)
J. W. Roe (1941)

Junior Advisor: C. F. Pray (1937)

(*Personnel of Special Committee, p.* RI-5)

EDUCATION AND TRAINING FOR THE INDUSTRIES

C. J. Freund, *Chairman and Representative on Council* (1937)
John Younger (1938) Warner Seely (1940)
J. A. Randall (1939) J. H. Ploehn (1941)

RELATIONS WITH COLLEGES

R. V. Wright, *Chairman and Representative on Council* (1937)
W. A. Hanley (1938) H. O. Croft (1940)
F. V. Larkin (1939) E. W. O'Brien (1941)

W. J. Cope, R. L. Daugherty, R. H. G. Edmonds — *Advisory Members* (1937)

Junior Advisor: H. B. Fernald, Jr. (1937)

(*Student Branches and Officers, p.* RI-8)

LIBRARY

L. K. Sillcox, *Chairman and Representative on Council* (1937)
J. S. Kerins (1938) A. R. Mumford (1940)
The Secretary, C. E. Davies, *Ex-Officio*

RESEARCH

Organized in 1909 to supervise all research activities of the Society, to cooperate with similar committees of kindred societies, to encourage research, and to disseminate knowledge of researches conducted in the United States and in other countries

N. E. Funk, *Chairman and Representative on Council* (1939)
J. E. Gleason (1937) L. W. Wallace (1940)
H. A. Johnson (1938) E. G. Bailey (1941)

(*Personnel of Special Committees, p.* RI-17)

STANDARDIZATION

Organized in April, 1911, to supervise all standardization activities of the Society and to advise concerning the Society's participation in the activities of the American Standards Association

Walter Samans, *Chairman and Representative on Council* (1938)
J. E. Lovely (1937) W. C. Mueller (1940)
O. A. Leutwiler (1939) A. L. Baker (1941)

(*Personnel of Special Committees, p.* RI-19)

POWER TEST CODES

Organized December, 1918, to revise and extend the Power Test Codes of the Society. These codes had been formulated by various technical committees appointed to develop particular codes. This work began in 1886.

R. H. Fernald, *Chairman and Representative on Council* (1940)

Francis Hodgkinson, *Vice-Chairman*
W. G. Rothschild, *Junior Observer* (1937)

Term expires 1937
Harte Cooke
E. R. Fish
O. P. Hood

REGULAR NOMINATING COMMITTEE FOR 1937

GROUP

I Charles M. Allen, Worcester, Mass., *Chairman*
T. H. Beard, Bridgeport, Conn., *Alternate*

II F. M. Gibson, Brooklyn, N. Y., *Secretary*
E. G. Bailey, New York, N. Y., *1st Alternate*
W. E. Caldwell, New York, N. Y., *2nd Alternate*

III A. L. DeLeeuw, Plainfield, N. J.
Virgil M. Palmer, Rochester, N. Y., *Alternate*

IV B. E. Short, Austin, Texas
J. W. Eshelman, Birmingham, Ala., *Alternate*

V L. E. Jermy, Cleveland, Ohio
G. A. Young, Lafayette, Ind., *1st Alternate*
K. F. Treschow, Pittsburgh, Pa., *2nd Alternate*

VI A. A. Luebs, Lincoln, Neb.
C. F. Moulton, Omaha, Neb., *1st Alternate*
W. L. DeBaufre, Lincoln, Neb., *2nd Alternate*

VII J. C. Othus, Corvallis, Ore.
Paul L. Heslop, Portland, Ore., *1st Alternate*
Franklin L. Davis, Portland, Ore., *2nd Alternate*

LOCAL SECTIONS IN NOMINATING COMMITTEE GROUPS

GROUP I

Boston, Bridgeport, Green Mountain, Hartford, Meriden, New Britain, New Haven, Norwich, Providence, Waterbury, Western Massachusetts, Worcester

GROUP II

Metropolitan (N. Y.) and Foreign Members

GROUP III

Anthracite-Lehigh Valley, Baltimore, Central Pennsylvania, Ithaca, Philadelphia, Plainfield, Rochester, Schenectady, Susquehanna, Syracuse, Utica, Washington, D. C.

GROUP IV

Atlanta, Birmingham, Charlotte, Chattanooga, Florida, Greenville, Knoxville, Memphis, New Orleans, North Texas, Raleigh, Savannah, South Texas, Virginia

GROUP V

Akron-Canton, Buffalo, Central Indiana, Cincinnati, Cleveland, Columbus, Dayton, Detroit, Erie, Louisville, Ontario, Peninsula, Pittsburgh, Toledo, West Virginia, Youngstown

GROUP VI

Chicago, Kansas City, Mid-Continent, Milwaukee, Minnesota, Nebraska, Rock River Valley, St. Joseph Valley, St. Louis, Tri-Cities

GROUP VII

Colorado, Inland Empire, Los Angeles, Oregon, San Francisco, Utah, Western Washington

Special Council Committees

ADVISORY BOARD ON PROFESSIONAL STATUS

H. R. Westcott, *Chairman*
C. F. Hirshfeld, Engineers' Council for Professional Development
R. H. McLain, Admissions
V. M. Palmer, Registration
B. F. Wood, Professional Conduct

ADVISORY BOARD ON STANDARDS AND CODES

Alex D. Bailey, *Chairman*
V. M. Frost, Boiler Code
W. M. Graff, Safety
Francis Hodgkinson, Power Test Codes
O. A. Leutwiler, Standardization

ADVISORY BOARD ON TECHNOLOGY

Alfred Iddles, *Chairman*
G. F. Bateman, Publications
H. N. Davis, Meetings and Program
Crosby Field, Professional Divisions
L. W. Wallace, Research

AIMS AND OBJECTIVES

Alfred Iddles, *Chairman*; F. E. Cardullo; W. L. Edel; E. E. Howard; L. E. Jermy; R. G. Macy; E. W. O'Brien; G. B. Pegram; Elgin Stoddard

Ex-Officio

A. D. Bailey, Board on Standards and Codes
W. D. Ennis, Finance
J. P. Harbeson, Jr., Speaker, Delegates Conference, Annual Meeting
Alfred Iddles, Board on Technology
H. R. Westcott, Board on Professional Status

BOARD OF REVIEW (DELINQUENT MEMBERS)

J. P. Neff, *Chairman*; C. P. Bliss; S. D. Sprong

TRUSTEES FOR CERTIFICATES OF INDEBTEDNESS

W. D. Ennis; Erik Oberg; R. V. Wright

CITIZENSHIP (MANUAL ON)

A. R. Cullimore, *Chairman*; Lillian M. Gilbreth; J. W. Roe; W. H. Winterrowd; R. V. Wright

DEVELOPMENT

D. S. Kimball, *Chairman*; E. G. Bailey; W. S. Finlay, Jr.; G. A. Orrok; C. G. Spencer

ECONOMIC STATUS OF THE ENGINEER

C. F. Hirshfeld, *Chairman*; D. S. Kimball; C. N. Lauer; H. B. Oatley; H. L. Whittemore; W. E. Wickenden
Chairmen of Committees on Local Sections and Relations with Colleges — *Ex-Officio*

FREEMAN SCHOLARSHIP

Charles T. Main, *Chairman*; Clarke Freeman; E. C. Hutchinson

MANUAL OF PRACTICE

B. F. Wood, *Chairman*; Alfred Iddles; Wynn Meredith; J. M. Todd; M. X. Wilberding; E. R. Fish, *Ex-Officio*
Theodore Baumeister, Jr., *Acting Secretary*
Junior Advisor, Philip Werner

Drying, C. W. Thomas
Food Processing, G. L. Montgomery
Industrial Instruments and Regulators, Ed S. Smith
Pulp and Paper, H. D. Fisher
Sanitation, William Raisch
Sugar, F. M. Gibson
Unit Operation Costs, H. J. Masson

HEAT TRANSFER COMMITTEE

J. H. Sengstaken, *Chairman*
W. S. Patterson, *Secretary*
R. E. Birch
Thos. Drew
E. D. Grimison
H. C. Hottel
C. E. Lucke
A. K. Scott
M. S. Van Dusen

Railroad Division

Organized, 1920

EXECUTIVE COMMITTEE

W. H. Winterrowd, *Chairman*
C. T. Ripley, *1st Vice-Chairman*
E. C. Schmidt, *2nd Vice-Chairman*
L. H. Fry, *3rd Vice-Chairman*
A. I. Lipetz, *4th Vice-Chairman*
M. B. Richardson, *Secretary*

GENERAL COMMITTEE (RR2)

W. H. Winterrowd, *Chairman*
D. S. Ellis (1937)
Thos. C. McBride (1937)
K. F. Nystrom (1937)
W. H. Clegg (1938)
F. G. Lister (1938)
G. A. Young (1938)
Harvey Boltwood (1939)
Frank E. Russell (1939)
R. W. Salisbury (1939)
O. C. Cromwell (1940)
W. E. Dunham (1940)
J. R. Jackson (1940)
A. Giesl-Gieslingen (1941)
L. W. Wallace (1941)
E. G. Young (1941)

PAST-CHAIRMEN (RR3)

E. B. Katte * (1920-1922)
James Partington (1923-1924)
C. E. Chambers (1925)
H. B. Oatley (1926-1927)
Wm. Elmer (1928)
R. S. McConnell (1929)
A. F. Steubing (1930)
Eliot Sumner (1931)
T. C. McBride (1932)
L. K. Sillcox (1933)
C. B. Peck (1934)
C. E. Barba (1935)
Geo. W. Rink (1936)

CHICAGO GROUP (RR4)

Peter Parke, *Chairman*
E. L. Woodward, *Secretary*
Walter Dunham
W. O. Moody
C. T. Ripley
W. H. Winterrowd

COMMITTEE ON MEETINGS AND PAPERS (RR5)

W. E. Dunham, *Chairman*
J. R. Jackson

COMMITTEE ON SURVEY (RR6)

A. Giesl-Gieslingen, *Chairman* (Locomotive and Foreign Developments)
W. H. Clegg (Canadian and Automotive Equipment)
K. F. Nystrom (Cars)

COMMITTEE ON RESEARCH (RR9)

A. F. Steubing, *Chairman*
W. G. Dickerman
William Elmer
L. H. Fry
C. B. Peck
L. W. Wallace
W. H. Winterrowd

* Deceased

Textile Division

Organized, 1921

EXECUTIVE COMMITTEE

A. W. Benoit, *Chairman*
H. D. Learnard, *Vice-Chairman*
M. A. Golrick, Jr., *Secretary*
Wendell Brown
R. DeVere Hope
Albert Palmer

Associates

J. J. McElroy
Clifford H. Ramsey
Earl Stall

Wood Industries Division

Organized, 1921

EXECUTIVE COMMITTEE

A. W. Keuffel, *Chairman*
L. M. Nichols, *Secretary*
T. D. Perry
R. H. McCarthy
P. T. Norton, Jr.

Associates

C. L. Babcock
P. H. Bilhuber
H. B. Carpenter
P. P. Cartwright
A. S. Kurkjian
Sern Madsen
J. H. Mansfield
J. S. Mathewson
G. R. Petrie
A. D. Smith

MACHINING OF WOOD COMMITTEE

R. H. McCarthy, *Chairman*
C. L. Babcock
E. M. Davis
G. E. French
W. Kynoch
C. M. Thompson

Student Branches

(*Personnel of Standing Committee on Relations With Colleges, page* RI-2. *Communicate with Student Branch through Honorary Chairman*)

Name and Location	Year Authorized	Chairman	Secretary	Honorary Chairman

* *Faculty Advisor.*

Local Sections

(Personnel of Standing Committee, p. RI-1)

Mid-West Office

Room 1617, 205 West Wacker Drive, Chicago, Ill.

Mid-Continent Office

J. H. Engelbrecht, Mid-Continent Petroleum Secretary, 102 Tulsa Bldg., Tulsa, Okla.

Regional Group Delegates to Annual Conferences

Terms expire October, 1937

W. L. Edel, Group I
Theo. Baumeister, Jr., Group II
R. S. Brescka, Group III
S. B. Earle, Group IV
S. R. Beitler, Group V
R. M. Barnes, Group VI
D. R. Gray, Group VII

Terms expire October, 1938

J. P. Harbeson, Jr., *Speaker*, Group III
V. M. Frost, *Secretary*, Group II
A. L. Davis, Group I
L. J. Lassalle, Group IV
K. F. Treschow, Group V
C. A. Koepke, Group VI
E. O. Eastwood, Group VII

AKRON-CANTON

Organized: 1920
Territory: Counties of Richland, Ashland, Medina, Summit, Portage, Wayne, Stark, Holmes, Tuscarawas, Carroll, and Coshocton in Ohio
Number of Members: 123

Executive Committee

H. A. Trishman, *Chairman*
W. P. Cox, *Vice-Chairman*
James Forrest, *Secretary-Treasurer*
M. R. Bowerman
W. O. Clinedinst
E. C. Huge
E. F. Maas
R. H. Smith
H. E. Waner
C. D. Zimmerman

ANTHRACITE-LEHIGH VALLEY

Organized: 1920, as Lehigh Valley; reorganized, 1928, as Anthracite-Lehigh Valley
Territory: Counties of Bradford, Susquehanna, Wayne, Sullivan, Wyoming, Lackawanna, Columbia, Luzerne, Monroe, Pike, Schuylkill, Carbon, Berks, Lehigh, Northampton in Pennsylvania, and Warren in New Jersey
Place of Meeting: One meeting annually at Allentown, Bethlehem, Easton, Hazleton, Pottsville, Reading, Scranton, and Wilkes-Barre
Local Organization: The Engineers' Club of Lehigh Valley
Number of Members: 185

Executive Committee

P. B. Eaton, *Chairman*
F. H. Dechant, *Vice-Chairman*
H. A. Pickel, *Vice-Chairman*
C. W. Bell, *Secretary*
R. J. Prince, *Treasurer*
R. D. Berniger
A. B. Clemens
E. M. Fernald
W. W. Hagerty
C. H. McKnight
R. H. Porter
J. T. Rea
W. P. Saunier
J. W. Steinmeyer

ATLANTA

Organized: 1913
Territory: Radius of sixty miles from Atlanta, Ga.
Place of Meeting: Atlanta Athletic Club
Luncheon meeting every Monday at 12:30 P. M. at Atlanta Athletic Club
Number of Members: 69

Executive Committee

G. Braungart, Jr., *Chairman*
R. M. Matson, *Vice-Chairman*
M. F. Merl, *Secretary-Treasurer*
T. E. Bell
H. D. Emmert
S. C. Hale
R. Whitfield

BALTIMORE

Organized: 1916
Territory: Radius of thirty miles from Baltimore, Md.
Place of Meeting: Engineers' Club of Baltimore
Luncheon meeting every Wednesday at 12:00 noon at Engineers' Club
Number of Members: 144

Executive Committee

R. C. Dannettel, *Chairman*
K. P. Hanson, *Secretary-Treasurer*
C. R. Chisholm
L. F. Coffin
N. B. Higgins
J. C. Holtz
F. W. Kouwenhoven
A. L. Penniman
W. E. Proctor

BIRMINGHAM

Organized: 1915
Territory: Radius of sixty miles from Birmingham, Ala.
Place of Meeting: Tutwiler Hotel
Number of Members: 59

Executive Committee

T. J. Carpenter, *Chairman*
G. R. Ozley, *Vice-Chairman*
D. H. Guldberg, *Secretary-Treasurer*
Neal Dugger
J. W. Eshelman

BOSTON

Organized: 1909
Territory: Radius of thirty miles from Boston, Mass.
Place of Meeting: Rooms of the Engineering Societies of New England
Local Organization: Engineering Societies of New England
Number of Members: 521

Executive Committee

George Eaton, *Chairman*
E. L. Root, *Vice-Chairman*
B. B. Fogler, *Secretary*
H. K. Dean
James Holt
G. F. Jenks

BRIDGEPORT

Organized: 1917, as a Branch of Connecticut Section; reorganized as a Section, 1923
Territory: Fairfield County, Conn.
Place of Meeting: Stratfield Hotel
Local Organization: Engineers' Club of Bridgeport
Number of Members: 127

Executive Committee

C. N. Hoagland, *Chairman*
O. J. Richmond, *Vice-Chairman*
W. H. Sniffen, *Secretary*
A. W. Hagan, *Treasurer*
T. H. Beard
J. Brenzinger
Arthur Brewer
W. R. Clark
A. H. Emery
H. Patterson Harris
R. C. Moody
H. E. Wells

BUFFALO

Organized: 1915
Territory: Radius of thirty miles from Buffalo, N. Y.
Place of Meeting: Hotel Statler
Local Organization: Engineering Society of Buffalo
Number of Members: 166

Executive Committee

J. L. Yates, *Chairman*
Paul Dubosclard, *Vice-Chairman*
W. A. Miller, *Secretary*
C. E. Harrington, *Treasurer*
Carl Rosa
W. M. Kauffman
E. K. Nicholson

CENTRAL INDIANA

Organized: 1916
Territory: Radius of eighty miles from Indianapolis, within Indiana
Place of Meeting: Place varies
Local Organization: Indiana Engineering Society
Number of Members: 112

Executive Committee

F. C. Hockema, *Chairman*
F. R. Weaver, *Vice-Chairman*
J. C. Siegesmund, *Secretary-Treasurer*
James Cunning
Homer Rupard

CENTRAL PENNSYLVANIA

Organized: 1921
Territory: Radius of approximately sixty miles from State College, Pa.
Place of Meeting: Pennsylvania State College, State College, Pa.
Number of Members: 82

Executive Committee

C. H. Kent, *Chairman*
F. Stewart, *Secretary*
H. A. Everett
John Henzey

CHARLOTTE

Organized: As a Branch, 1923; as a Section, 1927
Territory: Radius of seventy-five miles from Charlotte, N. C.
Luncheon Meeting every Monday at 1:00 P.M. at Efirds Department Store
Number of Members: 35

Executive Committee

W. E. McDowell, *Chairman*
V. E. Fuller, *Vice-Chairman*
W. W. Leroy, *Secretary-Treasurer*
Asa Hosmer
R. W. Olive

CHATTANOOGA

Organized: 1922
Territory: Radius of sixty miles from Chattanooga, Tenn.
Local Organization: Chattanooga Engineers' Club
Luncheon meeting every Monday noon at Chattanooga Engineers' Club
Number of Members: 15

Executive Committee

Newell Sanders, *Chairman*
H. H. Bailey, *Vice-Chairman*
F. Ward Reilly, *Secretary-Treasurer*
L. G. Haller
M. P. Wall

CHICAGO

Organized: 1913
Territory: Radius of fifty miles from Chicago, Ill.
Headquarters: Mid-West A.S.M.E. Office, Room 1617, 205 West Wacker Drive, Chicago, Ill.
Luncheon Meeting every Tuesday at 12:15 P. M. at Chicago Engineers' Club
Local Organization: Western Society of Engineers
Number of Members: 698

Executive Committee

T. S. McEwan, *Chairman*
W. E. Dunham, *Vice-Chairman*
F. B. Orr, *Secretary-Treasurer*
R. D. Brizzolara
C. B. Cole
L. A. Clousing
Hugo Diemer
Nixon Elmer
J. S. Kozacka
F. H. Lane
Adolph Langsner
C. T. Link, Jr.
D. Roesch
Edward R. Rowley
R. E. Turner
W. H. Winterrowd
E. L. Woodward

CINCINNATI

Organized: 1912
Territory: Radius of thirty miles from Cincinnati, Ohio
Place of Meeting: Engineers' Club Rooms, Ninth & Race Sts.
Local Organization: Engineers' Club of Cincinnati
Number of Members: 177

Executive Committee

F. E. Cardullo, *Chairman*
H. C. Uihlein, *Vice-Chairman*
C. A. Joerger, *Secretary-Treasurer*
D. Brown
W. E. M. Fielman
C. L. Koehler
Edward Martin
L. F. Nenninger
R. S. Parker
F. H. Pfefferle

CLEVELAND

Organized: 1918
Territory: Counties of Lorain, Cuyahoga Lake, Geauga, and Ashtabula in Ohio
Place of Meeting: Statler Hotel
Local Organization: Cleveland Engineering Society
Luncheon Meeting every Wednesday at 12:30 P. M. at Hotel Statler Cafeteria
Number of Members: 250

Executive Committee

E. Stanley Ault, *Chairman*
F. Jehle, *Vice-Chairman*
E. R. McCarthy, *Secretary*
C. C. McClelland, *Treasurer*
J. Roland Brown
W. C. Connelly
C. A. Dauber
McRea Parker
C. C. Wales

COLORADO

Organized: 1919
Territory: Entire State of Colorado
Place of Meeting: Parisienne Rotisserie Inn, Denver, Colo.
Local Organization: Colorado Engineering Council (Colorado Society of Engineers)
Number of Members: 95

Executive Committee

R. W. Morton, *Chairman*
A. L. Hill, *Secretary-Treasurer*
L. D. Crain
J. A. Hunter
F. A. Lockwood
F. H. Prouty
G. A. Richter

COLUMBUS

Organized: 1920
Territory: Counties of Union, Delaware, Licking, Madison, Franklin, Fayette, Pickaway, and Ross in Ohio
Place of Meeting: Battelle Memorial Institute and Ohio State University
Local Organization: Engineers' Club of Columbus
Luncheon Meeting Third Friday of each month at 12:00 noon at Engineers' Club, Columbus
Number of Members: 74

Executive Committee

R. A. Sherman, *Chairman*
R. C. Cross, *Secretary-Treasurer*
S. R. Beitler
D. R. Croft
H. S. Dickerson
E. M. Sampson
W. A. Welcker, Jr.

DAYTON

Organized: 1926
Territory: Counties of Drake, Miami, Champaign, Preble, Montgomery, Greene, and northern part of Butler and Warren in Ohio
Place of Meeting: Engineers' Club of Dayton
Local Organization: Engineers' Club of Dayton
Number of Members: 75

Executive Committee

R. W. Martin, *Chairman*
G. A. Buvinger, *Vice-Chairman*
J. J. Healy, *Secretary*
B. E. Tate, Jr., *Treasurer*
R. K. Coppock
H. M. Gano
L. E. Hutsel
F. H. Williams

DETROIT

Organized: 1916
Territory: Radius of thirty miles from Detroit, Mich.
Place of Meeting: Place varies
Local Organization: Engineering Society of Detroit
Number of Members: 404

Executive Committee

L. T. Knocke, *Chairman*
C. J. Freund, *Secretary-Treasurer*
C. R. Alden
J. W. Armour
M. W. Benjamin
G. C. Daniels
C. L. Eksergian
J. J. Grebe
H. E. Keeler
A. F. Knoblock
E. T. Vincent
Sabin Crocker, *Ex-Officio*

ERIE

Organized: 1917
Territory: Radius of thirty miles from Erie, Pa.
Place of Meeting: Auditorium of Pennsylvania Telephone Company
Number of Members: 61

Executive Committee

B. S. Cain, *Chairman*
W. L. Hunter, *Vice-Chairman*
E. C. Ims, *Secretary*
C. T. Orgel, *Treasurer*
G. W. Bach
E. R. Gnade
G. Kaemmerling
H. G. Mueller
A. J. Woodward

FLORIDA

Organized: 1925
Territory: State of Florida
Place of Meeting: Place varies
Local Organization: Florida Engineering Society, Gainesville, Fla.
Number of Members: 75

Executive Committee

J. P. Warren, *Chairman*
B. R. Van Leer, *1st Vice-Chairman*
H. J. B. Scharnberg, *2nd Vice-Chairman*
N. C. Ebaugh, *Secretary-Treasurer*
C. Beensen
C. H. Bolton, Jr.
C. V. Imeson
C. M. Lowry
Erling Riis
W. H. Toske

GREEN MOUNTAIN

Organized: 1923
Territory: Entire State of Vermont and neighboring and closely related communities of Claremont and Hanover, N. H.
Place of Meeting: Springfield, Windsor, Vt., and Claremont, N. H.
Local Organization: Vermont Engineering Society
Number of Members: 34

Executive Committee

C. J. Dewell, *Chairman*
M. H. Arms, *Secretary-Treasurer*
C. H. Adams
C. S. Beach
R. W. Haskel
J. B. Johnson
F. A. Joy
H. J. Lockwood
E. L. Sussdorff

GREENVILLE

Organized: As a Branch, 1923; as a Section, 1927
Territory: Radius of sixty miles from Greenville, S. C.
Place of Meeting: Meetings held at Greenville, Clemson College, S. C., Canton, Asheville, and Enka, N. C.
Number of Members: 41

Executive Committee

R. S. Pruitt, *Chairman*
J. A. McPherson, *Vice-Chairman*
J. B. Mayo, *Secretary-Treasurer*
B. E. Fernow
H. H. Iler
G. R. Morgan
E. R. Stall
F. A. Wayant

HARTFORD

Organized: 1917, as Branch of Conn. Section; reorganized, 1923
Territory: Hartford County except that portion served by Meriden and New Britain Sections
Place of Meeting: Hartford Electric Light Company
Number of Members: 115

Executive Committee

E. P. Herrick, *Chairman*
G. R. Truedsson, *Vice-Chairman*
D. K. Morgan, *Secretary-Treasurer*
R. F. Dow
F. O. Hoagland
R. D. Keller
W. S. Paine
R. S. Shaw
S. Jay Teller
H. B. VanZelm
J. C. Ward, Jr.

INLAND EMPIRE

Organized: 1921
Territory: East of Columbia River in State of Washington, and Counties of Okanogan and Benton, and part of Northern Idaho
Place of Meeting: Davenport Hotel, Spokane
Luncheons Wednesdays at 12:00 noon, Davenport Hotel, Spokane
Local Organization: Associated Engineers of Spokane
Number of Members: 26

Executive Committee

H. H. Langdon, *Chairman*
Henry Gauss, *Vice-Chairman*
C. I. Carpenter, *Secretary-Treasurer*
D. R. Gray
L. J. Pospisil

ITHACA

Organized: 1936. Organizing Officer: F. G. Switzer

KANSAS CITY

Organized: 1921
Territory: Radius of sixty miles from Kansas City, Mo.
Place of Meeting: President Hotel
Local Organization: Engineers' Club of Kansas City
Number of Members: 105

Executive Committee

H. A. Smith, *Chairman*
L. Helander, *Vice-Chairman*
H. L. Crain, *Secretary*
W. B. Rollins, *Treasurer*
J. A. King
W. L. Mathews
J. F. Pritchard
J. R. Stone
H. W. Williamson

KNOXVILLE

Organized: 1923
Territory: All the counties east of the west boundaries of the following: Morgan, Roane, Loudon, McMinn, Scott, and Polk, Tenn., and Bell County, Ky.
Place of Meeting: Andrew Johnson Hotel
Local Organization: Knoxville Technical Club
Number of Members: 68

Executive Committee

John Callan, *Chairman*
F. L. Wilkinson, *Vice-Chairman*
R. Brooks Taylor, *Secretary-Treasurer*
C. Daniels
J. M. Kaderly
T. I. Stephenson

LOS ANGELES

Organized: 1915
Territory: South of southern boundaries of following counties: Monterey, Kings, Tulares, and Inyo, Calif.
Place of Meeting: Ninth floor, Chamber of Commerce Bldg.
Local Organization: Technical Societies of Los Angeles
Luncheon Meetings Thursdays at 12:00 noon at Engineers' Club
Number of Members: 374

Executive Committee

H. L. Eggleston, *Chairman*
S. W. Duncan, *Vice-Chairman*
S. M. Dunn, *Secretary-Treasurer*
R. McC. Beanfield
F. M. Beeson
C. W. Coberly
H. S. Ingham

LOUISVILLE

Organized: 1922
Territory: Radius of thirty miles from Louisville, Ky.
Place of Meeting: Engineers' and Architects Club of Louisville
Local Organization: Engineers' and Architects Club
Number of Members: 44

Executive Committee

J. H. Romann, *Chairman*
L. R. Jackson, *Vice-Chairman*
H. H. Fenwick, *Secretary-Treasurer*
B. M. Brigman
G. W. Hubley
John F. Hurst

MEMPHIS

Organized: 1923
Territory: Radius of sixty miles from Memphis, Tenn.
Number of Members: 20

Executive Committee

M. W. Rice, *Chairman*
W. J. Fransioli, Jr., *Secretary-Treasurer*
D. F. Brooks
W. Roberts
M. D. Rust

MERIDEN

Organized: 1917, as a Branch of Connecticut Section; reorganized as a Section, 1923
Territory: Meriden, Middletown, Southington, Portland, Plantsville, and Wallingford, Conn.
Place of Meeting: State Trade School Auditorium
Number of Members: 13

Executive Committee

C. A. Newton, *Chairman*
R. W. Stetson, *Secretary-Treasurer*
E. L. Barker
J. A. Hutchinson
L. B. Marcy
E. A. Robinson
Philip Tripoli
J. C. Tucker

METROPOLITAN

Organized: 1910
Territory: Metropolitan District, New York and New Jersey
Place of Meeting: Engineering Societies Building, New York, N. Y.
Number of Members: 3426

Executive Committee

T. Baumeister, Jr., *Chairman*
C. A. Hescheles, *Secretary*
V. M. Frost, *Treasurer*
J. M. Driscoll
A. Ernst
W. C. Glass
John Hoffhine
T. E. Keating
G. W. Kelsey
J. N. Landis, *Ex-Officio*

MID-CONTINENT

Organized: 1919
Territory: Entire states of Oklahoma and Arkansas, and a part of Louisiana. In Texas north of the southern boundaries of the counties of Gaines, Dawson, Bordon, Scurry, Fisher, Jones, and Shackelford
Place of Meeting: 102 Tulsa Bldg., Tulsa, Okla.
Number of Members: 124

Executive Committee

R. G. Ayers, *Chairman*
J. H. Keyes, *Vice-Chairman*
E. Kemler, *Secretary*
C. H. Keplinger, *Treasurer*
A. J. Mack
B. Oakland
L. C. Price
W. H. Stueve

MILWAUKEE

Organized: 1904
Territory: Radius of fifty miles from Milwaukee, Wis.
Place of Meeting: Milwaukee Athletic Club
Local Organization: Engineers' Society of Milwaukee
Number of Members: 190

Executive Committee

L. H. Stark, *Chairman*
T. F. Eserkaln, *Secretary*
W. D. Bliss
H. Dahlstrand
Fred Dorner
A. H. Luedicke
Arthur Simon

MINNESOTA

Organized: Minneapolis, 1913; St. Paul, 1913; the two Sections merged, 1934
Territory: Entire State of Minnesota
Place of Meeting: Minnesota Union
Local Organization: Minneapolis Engineers' Club, Minnesota Federation of Architectural and Engineering Societies
Number of Members: 86

Executive Committee

L. A. Cobb, *Chairman*
C. A. Koepke, *Vice-Chairman*
A. R. Ford, *Secretary-Treasurer*
George Endicott
Melvin Ovestrud
Harold Washburn

NEBRASKA

Organized: 1922
Territory: State of Nebraska, and Council Bluffs, Iowa
Place of Meeting: Lincoln and Omaha
Local Organization: Engineers' Club of Lincoln and Omaha
Luncheon Meeting every Wednesday noon at the Omaha Engineers' Club
Number of Members: 32

Executive Committee

C. F. Moulton, *Chairman*
A. E. Bunting, *Vice-Chairman*
A. A. Luebs, *Secretary-Treasurer*
W. L. DeBaufre
Otto Jabelmann
L. J. Ruf

NEW BRITAIN

Organized: 1921, as a Branch of Connecticut Section; reorganized as a Section, 1923
Territory: New Britain, Plainville, Forestville, Bristol, Kensington, and Berlin, Conn.
Place of Meeting: Auditorium of the State Trade School
Number of Members: 39

Executive Committee

P. W. Bauer, *Chairman*
C. C. Stevens, *Vice-Chairman*
H. L. Potter, *Secretary-Treasurer*
R. A. Grise
N. F. Hjerpe
B. S. Lewis
C. W. Lund
A. R. Spicacci

NEW HAVEN

Organized: 1912; reorganized, 1923
Territory: Portions of New Haven and Middlesex Counties, Conn.
Place of Meeting: Mason Laboratory, Yale University
Number of Members: 75

Executive Committee

H. R. Polleys, *Chairman*
M. J. Radecki, *Secretary-Treasurer*
Albert F. Breitenstein
F. W. Keator
R. A. North
W. F. Thompson
L. H. Von Ohlsen

NEW ORLEANS

Organized: 1916
Territory: All of Louisiana except the northern part allotted to Mid-Continent Section
Place of Meeting: Room 422, St. Charles Hotel
Local Organization: Louisiana Engineering Society
Number of Members: 88

Executive Committee

C. C. Crawford, *Chairman*
L. J. Lassalle, *Vice-Chairman*
G. R. Hammett, *Secretary-Treasurer*
J. S. Huey
R. F. Muller

NORTH TEXAS

Organized: 1922
Territory: Radius of one hundred and twenty-five miles from Dallas, in Texas
Place of Meeting: Dallas Power & Light Co. Bldg.
Local Organization: Technical Club of Dallas
Number of Members: 80

Executive Committee

R. R. Crowdus, *Chairman*
H. R. Pearson, *Secretary*
E. W. Burbank
P. M. Cordell
J. A. Noyes
H. M. Robinson

NORWICH

Organized: 1930
Territory: Counties of Tolland, Windham, and New London in Connecticut, and Westerly District in Rhode Island
Place of Meeting: Arcanum Club, 150 Main St., Norwich
Number of Members: 33

Executive Committee

C. W. Phelps, *Chairman*
W. E. Beaney, *Secretary-Treasurer*
C. E. Barber
A. E. Welch
L. E. Whiton
W. L. Edel, *Ex-Officio*

ONTARIO

Organized: 1917
Territory: Province of Ontario, Canada
Place of Meeting: Mining Building, University of Toronto
Number of Members: 112

Executive Committee

W. S. Ball, *Chairman*
F. G. East, *Secretary-Treasurer*
T. C. Agnew
J. R. Burgess
C. H. McL. Burns
C. C. Cariss
S. G. Clarke
F. H. Eland
O. W. Ellis
W. G. McIntosh
W. A. Richards
P. G. Welford

OREGON

Organized: 1919
Territory: State of Oregon and that territory in Washington within a radius of thirty miles from Portland, Ore.
Place of Meeting: Portland Hotel, Portland, Ore.
Local Organization: Oregon Society of Engineers
Number of Members: 56

Executive Committee

Paul Heslop, *Chairman*
Rodney Dunlop, *Secretary*
Wm. Brennan
G. O. Matter
J. C. Othus

PENINSULA

Organized: 1923
Territory: West of the east boundaries of the following counties: Emmet, Charlevoix, Antrim, Kalkaska, Missaukee, Clare, Isabella, Gratiot, Clinton, Eaton, Calhoun, and Branch, Mich.
Place of Meeting: Grand Rapids, Mich.
Local Organization: Engineers' Club of Grand Rapids
Number of Members: 39

Executive Committee

C. B. Norris, *Chairman*
L. A. Cornelius, *Vice-Chairman*
R. E. Klise, *Secretary-Treasurer*
Le Roy L. Benedict
A. Kurkjian

PHILADELPHIA

Organized: 1912
Territory: Counties of Bucks, Montgomery, Chester, Philadelphia, Delaware, Pa., and the State of Delaware
Place of Meeting: Philadelphia Engineers' Club, 1317 Spruce Street, Philadelphia, Pa.
Local Organization: Philadelphia Engineers' Club
Luncheon Meeting every Tuesday noon at Philadelphia Engineers' Club
Number of Members: 825

Executive Committee

J. P. Harbeson, Jr., *Chairman*
Coleman Sellers, 3rd, *Vice-Chairman*
C. C. Jones, *Secretary-Treasurer*
H. E. Corl
E. L. Hopping
W. F. Oberhuber

PITTSBURGH

Organized: 1920
Territory: Counties bounded by and including Beaver, Butler, Venango, Forest, Jefferson, Indiana, Somerset, Fayette, Greene, and Washington, Pa.
Place of Meeting: Engineers' Society of Western Pennsylvania, William Penn Hotel
Local Organization: Engineers' Society of Western Pennsylvania
Number of Members: 327

Executive Committee

H. E. Haller, *Chairman*
K. F. Treschow, *Secretary-Treasurer*
H. C. Clausen
G. E. Dignan
G. P. Ellis
J. A. Hunter

PLAINFIELD

Organized: 1921
Territory: Plainfield and territory included between Elizabeth, Bound Brook, Metuchen, and Watchung, N. J.
Place of Meeting: Elizabeth Carteret Hotel, Elizabeth, and Plainfield Masonic Temple, Plainfield
Local Organization: Plainfield Engineers Club, Singer Engineering Society
Number of Members: 183

Executive Committee

W. B. Updegraff, *Chairman*
R. S. Brescka, *Vice-Chairman*
G. E. Leavitt, Jr., *Secretary*
H. I. Lewis, *Treasurer*
J. P. Faber
D. V. Waters

PROVIDENCE

Organized: 1920
Territory: Radius of thirty miles from Providence, R. I.
Place of Meeting: Providence Engineering Society Building, 195 Angell St., Providence, R. I.
Local Organization: Providence Engineering Society
Number of Members: 163

Executive Committee

F. A. Chiffelle, *Chairman*
S. A. Vaule, *Vice-Chairman*
A. W. Calder, Jr., *Secretary-Treasurer*
F. S. Blackall, Jr.
Z. R. Bliss
A. C. Chick
E. W. Freeman
R. T. Ode
J. D. Robertson

RALEIGH

Organized: As a Branch, 1923; as a Section, 1927
Territory: Radius of sixty miles from Raleigh, N. C.
Place of Meeting: N. C. State College, Raleigh, N. C.
Local Organization: N. C. Engineering Council, Raleigh Engineers Club
Number of Members: 19

Executive Committee

R. M. Rothgeb, *Chairman*
R. S. Wilbur, *Vice-Chairman*
F. B. Turner, *Secretary-Treasurer*
E. G. Hoefer
R. Holt
C. E. Kerchner
H. H. Vance

ROCHESTER

Organized: 1919
Territory: Radius of thirty miles from Rochester, N. Y.
Place of Meeting: Rochester Engineering Society Rooms, Sagamore Hotel

Local Organization: Rochester Engineering Society, Sagamore Hotel
Luncheon Meeting every Tuesday at 12:15 P. M. at Sagamore Hotel
Number of Members: 100

Executive Committee

K. B. Castle, Jr., *Chairman*
Howard Harding, *Vice-Chairman*
J. G. McChesney, *Secretary-Treasurer*
W. T. Cowell
T. F. Hooker
M. D. Lee
W. D. Seeley

ROCK RIVER VALLEY

Organized: 1926
Territory: Radius of thirty miles from Rockford, Ill.
Local Organization: Rockford Engineering Society
Number of Members: 52

Executive Committee

H. Hall, *Chairman*
R. C. Glazebrook, *Vice-Chairman*
R. Hessellund, *Secretary-Treasurer*
L. Geddes
Herman Hugle
A. C. Mattison
W. R. Shedd

ST. JOSEPH VALLEY

Organized: 1929
Territory: Counties of La Porte, Starke, Pulaski, St. Joseph, Marshall, Fulton, Elkhart, and Kosciusko in Indiana, and Cass and Berrien Counties in Michigan
Place of Meeting: Morningside Hotel, South Bend, Ind.
Local Organization: St. Joseph Valley Engineers' Club
Number of Members: 26

Executive Committee

C. R. Adams, *Chairman*
C. C. Wilcox, *Vice-Chairman*
K. W. Knorr, *Secretary-Treasurer*

ST. LOUIS

Organized: 1909
Territory: Radius of thirty miles from St. Louis, Mo.
Place of Meeting: Place varies
Local Organization: Engineers' Club of St. Louis
Number of Members: 193

Executive Committee

G. L. Shanks, *Chairman*
P. H. Buxton, *Vice-Chairman*
E. H. Sager, *Secretary-Treasurer*
R. M. Boyles
David Larkin
A. J. Leussler

SAN FRANCISCO

Organized: 1910
Territory: All territory north of the northern boundaries of the counties of San Luis Obispo, Kern, and San Bernardino
Place of Meeting: Engineers' Club, 206 Sansome St.
Luncheon Meetings every Thursday at 12:00 noon at the Engineers' Club
Local Organization: San Francisco Engineers' Club
Number of Members: 332

Executive Committee

O. B. Lyman, *Chairman*
R. L. Grutzmacher, *Vice-Chairman*
K. B. Anderson, *Secretary-Treasurer*
C. V. Finch
F. E. Russell
G. L. Sullivan
F. W. Collins, *Ex-Officio*

SAVANNAH

Organized: 1923
Territory: Radius of 125 miles from Savannah in Georgia
Place of Meeting: Savannah Hotel
Local Organization: Engineers' Council of Savannah Chamber of Commerce
Number of Members: 17

Executive Committee

B. J. Sams, *Chairman*
L. C. Roesel, *Vice-Chairman*
T. R. Jones, *Secretary-Treasurer*
W. H. Artley
D. E. Kehoe
A. M. Ormond

SCHENECTADY

Organized: As a Branch, 1919; as a Section, 1927
Territory: Radius of thirty miles from Schenectady, N. Y.
Place of Meeting: Edison Club Hall
Number of Members: 153

Executive Committee

A. I. Lipetz, *Honorary-Chairman*
J. E. Anderson, *Chairman*
A. J. Larrecq, *Secretary*
J. K. Salisbury, *Treasurer*
B. O. Buckland
H. M. Otto
E. E. Parker
E. L. Robinson

SOUTH TEXAS

Organized: 1919
Territory: South Texas and the northern part of the State not included in the North Texas Section territory
Place of Meeting: Electric Bldg., Houston, Tex.
Number of Members: 120

Executive Committee

W. B. Preston, *Chairman*
B. E. Short, *Vice-Chairman*
J. J. King, *Secretary-Treasurer*
W. T. Alliger
D. D. Alton
F. G. D. Muller
J. H. Pound
F. D. Rahm
J. M. Robertson
W. W. Scott
W. B. Tuttle
R. M. Wingren

SUSQUEHANNA

Organized: 1927
Territory: Counties of Cumberland, Dauphine, Lebanon, Adams, York, and Lancaster
Place of Meeting: Engineering Society of York
Local Organization: Engineering Society of York and Engineers' Society of Pennsylvania, Harrisburg, Pa.
Number of Members: 75

Executive Committee

Alfred Jones, *Chairman*
C. G. A. Schmidt, Jr., *Vice-Chairman*
H. B. Martin, *Secretary*
E. D. Clark
A. Bowman Snavely
O. G. Wheat

SYRACUSE

Organized: 1920
Territory: Radius of thirty miles from Syracuse, N. Y.
Place of Meeting: Ball Room of the Onondaga Hotel
Local Organization: The Technology Club of Syracuse
Number of Members: 76

Executive Committee

E. W. Zimmerman, *Chairman*
M. B. Moyer, *Vice-Chairman*
D. V. Shetland, *Secretary-Treasurer*
D. W. Diefendorf
W. O. Hildreth
R. C. Paul
M. F. Williams

TOLEDO

Organized: 1920
Territory: Radius of thirty miles from Toledo, Ohio
Place of Meeting: University Club, Toledo, Ohio
Local Organization: Affiliated Technical Societies of Toledo
Number of Members: 50

Executive Committee

J. R. Emery, *Chairman*
E. L. McBee, *Vice-Chairman*
C. W. Kirsch, *Secretary-Treasurer*
H. W. Carter
Edward Farmer
H. O. Hem
H. H. Kerr
C. R. Pomeroy
E. W. Weaver

TRI-CITIES

Organized: 1920
Territory: Radius of thirty miles from Moline, Ill.
Place of Meeting: Rock Island, Ill., Moline, Ill., and Davenport, Iowa
Luncheon Meeting every Wednesday, Davenport Hotel, 12:00 Noon
Number of Members: 68

Executive Committee

R. M. Barnes, *Chairman*
J. H. Ploehn, *Vice-Chairman*
C. A. Carlson, *Secretary-Treasurer*
E. G. Erickson
J. M. Hartman
W. P. Hunt

UTAH

Organized: 1923
Territory: State of Utah
Place of Meeting: University Club, Salt Lake City
Local Organization: Utah Society of Engineers
Number of Members: 33

Executive Committee

J. Billeter, *Chairman*
J. D. Roberts, *Vice-Chairman*
W. D. Turpin, *Secretary-Treasurer*
W. J. Cope
E. W. Pace
N. L. Stewart

UTICA

Organized: 1920
Territory: Radius of thirty miles from Utica, N. Y.
Local Organization: Mohawk Valley Technical Club
Number of Members: 13

Executive Committee

E. G. Munson, *Chairman*
Rex Witherbee, *Secretary-Treasurer*
W. J. Clement

VIRGINIA

Organized: 1919
Territory: State of Virginia
Place of Meeting: Richmond, Norfolk, Charlottesville, Roanoke, University, Petersburg
Local Organization: Central Virginia Engineers Club
Number of Members: 122

Executive Committee

E. B. Norris, *Chairman*
A. F. Keane, *Vice-Chairman*
J. B. Jones, *Secretary*
N. W. Conner, *Treasurer*
C. H. Harris
J. B. Jones
E. F. Kroner
E. W. Miller
F. T. Morse
J. B. Woodward, Jr.

WASHINGTON, D. C.

Organized: 1919
Territory: District of Columbia
Place of Meeting: Auditorium, Potomac Electric Power Co., 10th & E Sts., Washington, D. C.
Number of Members: 189

Executive Committee

M. X. Wilberding, *Chairman*
J. Fulton Fox, *Vice-Chairman*
W. B. Ensinger, *Secretary-Treasurer*
J. G. Adair
Andrew T. Dupont
H. G. Thielscher
M. E. Weschler

WATERBURY

Organized: 1917, as a Branch of Connecticut Section; reorganized as a Section, 1923
Territory: Litchfield County and a portion of New Haven County
Place of Meeting: Elton Hotel
Number of Members: 81

Executive Committee

A. L. Davis, *Chairman*
L. G. Bean, *Vice-Chairman*
C. W. Rush, *Secretary-Treasurer*
M. J. Dempsey
R. L. Palatine
R. C. Perry

WESTERN MASSACHUSETTS

Organized: 1922
Territory: Includes counties of Berkshire, Franklin, Hampden, and Hampshire
Place of Meeting: Highland Hotel, Springfield, Mass.
Local Organization: Engineering Society of Western Massachusetts
Number of Members: 84

Executive Committee

C. E. Maynard, *Chairman*
D. W. Williamson, *Vice-Chairman*
L. G. Carlton, *Secretary-Treasurer*
Lester Campbell
J. C. Robinson
R. L. Bosworth, *Ex-Officio*

WESTERN WASHINGTON

Organized: 1919
Territory: State of Washington west of the Columbia River with the exception of the territory included in the thirty-mile radius of Portland, Ore.
Place of Meeting: Engineers' Club, Arctic Bldg., Seattle, Wash.
Local Organization: Seattle Engineers' Club
Luncheon Meetings daily at noon at Engineers' Club, Seattle, Wash.
Number of Members: 91

Executive Committee

R. L. Dyer, *Chairman*
E. I. Flateboe, *Vice-Chairman*
R. E. Walter, *Secretary-Treasurer*
D. F. Bartholet
Barton Cruikshank
Wm. R. Gibson
H. E. Peters
E. O. Eastwood, *Ex-Officio*

WEST VIRGINIA

Organized: 1925
Territory: State of West Virginia, South of Parallel 39
Place of Meeting: Charleston, W. Va.
Number of Members: 64

Executive Committee

E. L. Hudson, *Chairman*
J. F. Malloy, *Secretary-Treasurer*
H. B. Hickman, *Assistant Secretary*
E. R. Habicht
L. D. Hayes
J. H. Jaecker
O. C. Lange
R. E. Walker

WORCESTER

Organized: 1915
Territory: Radius of thirty miles from Worcester, Mass.
Place of Meeting: Sanford Riley Hall, Worcester Poly. Inst.
Local Organization: Worcester Engineering Society
Number of Members: 139

Executive Committee

R. Erickson, *Chairman*
C. P. Howard, *Vice-Chairman*
W. S. Snow, *Secretary-Treasurer*
D. G. Downing
R. F. Gow
S. N. McCaslin
O. Muller
F. W. Roys
E. R. Spaulding

YOUNGSTOWN

Organized: 1928
Territory: Counties of Trumbull, Mahoning, and Columbiana in Ohio, and Mercer and Lawrence in Pennsylvania
Place of Meeting: Central Y.M.C.A., Youngstown, Ohio
Number of Members: 52

Executive Committee

Erling Oyen, *Chairman*
G. Warren, *Vice-Chairman*
C. W. Foard, *Secretary-Treasurer*
F. Bowers
E. Davenport
L. A. Klein
A. G. McHugh
H. W. Smith
J. L. Wick

Special Research Committees

(Personnel of Standing Committees, p. RI-2)

LUBRICATION

Appointed October, 1915, to investigate the fundamental problems of lubrication, to formulate results of investigations previously made, and to keep in touch with contemporary research in this field

(Reorganized May, 1936)

G. B. Karelitz, *Chairman*
S. J. Needs, *Secretary*
A. L. Beall
Oscar Bridgeman
W. E. Campbell
Hans Dahlstrand
H. A. Everett
A. E. Flowers
R. C. Geniesse
Raymond Haskell
M. D. Hersey
L. P. Michael
G. L. Neely
B. L. Newkirk
A. E. Norton
J. F. Pelley
E. Wooler

FLUID METERS

Appointed 1916 to develop the theory of fluid meters of all kinds and to report on the best methods for their installation and use

(Reorganized July, 1926)

R. J. S. Pigott, *Chairman*
J. R. Carlton, *Secretary*
H. S. Bean
S. R. Beitler
R. K. Blanchard
W. W. Frymoyer
Louis Gess
T. H. Kerr
W. S. Pardoe
E. S. Smith, Jr.
R. E. Sprenkle
E. C. M. Stahl
T. R. Weymouth
M. J. Zucrow

THERMAL PROPERTIES OF STEAM

Appointed in December, 1921, to direct research on the thermal properties of water-vapor and steam from 0 C to the upper limits of temperature and pressure

(Reorganized April, 1929)

G. L. Bourne, *Chairman*
W. L. Abbott, *Vice-Chairman*
H. N. Davis
H. C. Dickinson
Alex Dow
A. M. Greene, Jr.
R. C. H. Heck
D. S. Jacobus
J. H. Keenan
F. G. Keyes
L. S. Marks
G. A. Orrok
R. J. S. Pigott
H. V. Rasmussen
E. L. Robinson

STRENGTH OF GEAR TEETH

Appointed in December, 1921. Is investigating factors affecting the strength and life of gear teeth

R. E. Flanders, *Chairman*
C. H. Logue, *Secretary*
C. G. Barth
Earle Buckingham
A. M. Greene, Jr.
C. W. Ham
F. E. McMullen
E. W. Miller
Ernest Wildhaber

CUTTING OF METALS

Appointed in September, 1923. Is studying the problems of metal cutting, including tool materials, tool design, lubrication, cooling, and speeds and feeds

Coleman Sellers, 3d, *Chairman*
L. N. Gulick, *Secretary*
L. P. Alford
O. W. Boston
R. C. Deale
A. L. DeLeeuw
Malcolm F. Judkins

MECHANICAL SPRINGS

Appointed May, 1924, to determine the status of the mechanical-spring art, to promote and conduct necessary and adequate research, and to develop the art to the point of standardization

J. R. Townsend, *Chairman*
C. T. Edgerton, *Secretary*
C. E. Barba
W. G. Brombacher
R. W. Cook
W. T. Donkin
Rupen Eksergian
G. E. Hansen
Benjamin Liebovitz
David Lofts
(R. D. Brizzolara, *Alternate*)
A. N. Lukens
D. J. McAdam, Jr.
R. E. Peterson
J. B. Reynolds
J. W. Rockefeller, Jr.
B. W. St. Clair
M. F. Sayre
Keith Williams
J. Kaye Wood
F. P. Zimmerli
O. B. Zimmerman

ELEVATOR SAFETIES

Appointed June, 1924, as a subcommittee of the Sectional Committee on Safety Code for Elevators, to study the function and operation of elevator safeties and buffers and their associated mechanisms and to develop methods of test for the approval of elevator safety devices

D. J. Purinton, *Chairman*
O. P. Cummings, *Vice-Chairman*
J. A. Dickinson, *Secretary*
Bassett Jones
D. L. Lindquist
M. G. Lloyd
J. J. Matson
M. B. McLauthlin
W. S. Paine

EFFECT OF TEMPERATURE ON THE PROPERTIES OF METALS

Appointed December, 1924, as a joint research committee of the A.S.T.M. and the A.S.M.E. to encourage the investigation and accumulation of data on the properties of metals used in the mechanic arts at extremely high and low temperatures

(Total personnel, 75)

H. J. French, *Chairman*
N. L. Mochel, *Secretary*
R. H. Aborn
A. D. Bailey
F. E. Bash
R. A. Bull
E. S. Dixon
F. B. Foley
H. W. Gillett
H. J. Kerr
H. W. Maack
C. E. MacQuigg
D. J. McAdam, Jr.
P. E. McKinney
E. L. Robinson
A. E. White

BOILER FEEDWATER STUDIES

Appointed March, 1925, as a Joint Research Committee of the American Boiler Manufacturers Association, American Railway Engineering Association, American Water Works Association, Edison Electric Institute, the American Society for Testing Materials, and the A.S.M.E., to study methods of analysis and treatment of boiler feedwater for stationary and railroad practice

Executive Committee (Total personnel 42)

C. H. Fellows, *Chairman*
R. C. Bardwell, *Vice-Chairman*
J. B. Romer, *Secretary*
Edward Bartow
† A. G. Christie
R. E. Coughlin
B. J. Cross
Max Hecht
† C. F. Hirshfeld
W. F. Keenan, Jr.
F. N. Speller
M. F. Stack
E. H. Tenney
C. P. Van Gundy
† A. E. White
Abel Wolman

CONDENSER TUBES

Appointed May, 1925, to investigate and report on the causes of failure of tubes used in steam condensers and similar heat interchange apparatus

A. E. White, *Chairman*
Bert Houghton, *Vice-Chairman*
P. A. Bancel
D. K. Crampton
H. M. Cushing
R. E. Dillon
O. B. J. Fraser
J. R. Freeman, Jr.
V. M. Frost
C. F. Harwood
C. F. Hirshfeld
G. C. Holder
H. W. Leitch
E. F. Miller
W. B. Price
M. F. Stack
H. A. Staples
W. R. Webster
Director, Bureau of Engineering, U. S. Navy Department

† Official A.S.M.E. representatives serving on this committee.

BOILER FURNACE REFRACTORIES

Appointed June, 1925, to determine the principal factors governing the failure of refractories in various types of installations, to subject these factors to detailed experimental analysis, to undertake the formulation of suitability tests and, if necessary, to attempt to develop a suitable refractory to meet the needs of severe service

W. A. Carter, *Chairman*
S. H. Barnum
G. A. Bole
M. C. Booze
W. H. Fulweiler
C. B. Grady
R. A. Heindl
C. F. Hirshfeld
O. P. Hood
R. K. Hursh
N. E. Lewis
J. S. McDowell
(F. A. Harvey, *Alternate*)
S. J. McDowell
Percy Nicholas
S. M. Phelps
E. B. Powell
R. A. Sherman
R. B. Sosman
L. J. Trostel
G. B. Wilkes

WORM GEARS

Appointed May, 1927, to investigate certain problems in connection with the action of worm gear drives and to recommend improvements in their design, manufacture, and use

Earle Buckingham, *Chairman*
G. H. Acker
L. R. Buckendale
W. H. Himes
D. L. Lindquist
A. A. Ross
B. F. Waterman
Representative of Bureau of Engineering, U. S. Navy Department

VELOCITY MEASUREMENT OF FLUID FLOW

Appointed October, 1927, to sponsor the development of an absolute method for determining the velocity of the flow of fluids by means of the location of nodal points in wave systems

W. F. Durand, *Chairman*
T. R. Weymouth

MEASURES OF MANAGEMENT

Appointed March, 1928, to attempt the reconciliation of certain economic laws affecting production, to develop formulas for management, and to collect and report information on management research

W. E. Freeland, *Chairman*
F. E. Raymond, *Secretary*
J. H. Barber
T. H. Brown
R. C. Davis
G. E. Hagemann

ABSORPTION OF RADIANT HEAT IN BOILER FURNACES

Appointed April, 1928, to make a study of the absorption of radiant heat in boiler furnaces with the purpose of developing recommendations on improved furnace design

W. J. Wohlenberg, *Chairman*
E. G. Bailey
R. M. Gates
C. W. Gordon
E. L. Lindseth
G. A. Orrok
R. J. S. Pigott
John Van Brunt

HEAVY DUTY ANTI-FRICTION BEARINGS

Appointed March, 1929, to investigate the possibilities and limitations of anti-friction bearings when applied to roll necks of rolling mills

W. Trinks, *Chairman*
J. H. Hitchcock, *Secretary*
H. E. Brunner
W. R. Clark
H. H. Talbot
S. M. Weckstein
H. A. Winne

REMOVAL OF ASH AS MOLTEN SLAG FROM POWDERED-COAL FURNACES

Appointed March, 1929, to investigate the adding of fluxes as a means of increasing the fluidity of slag in boiler furnaces and thus permit its removal at operating furnace temperatures

K. M. Irwin, *Chairman*
Andrew Carnegie
T. G. Coghlan
H. M. Cushing
C. F. Hirshfeld
Percy Nicholls
E. B. Powell
P. B. Rice

STRENGTH OF VESSELS UNDER EXTERNAL PRESSURE

Appointed June, 1929, to develop reliable design data on the strength of cylindrical and spherical surfaces under external pressure, particularly with reference to jacketed vessels

W. D. Halsey, *Chairman*
Thomas Griswold, Jr.
F. V. Hartman
M. B. Higgins
T. McL. Jasper
A. W. Limont, Jr.
Carl Rigdon
H. E. Saunders
E. E. Shanor
J. H. Taylor
(F. S. G. Williams, *Alternate*)
D. B. Wesstrom
D. F. Windenburg

AUTOMATIC OIL PIPE LINE PUMPING STATIONS

Authorized March, 1930, to develop methods of automatic control for oil pipe line pumping stations

W. G. Heltzel, *Chairman*
J. N. Hunter, *Vice-Chairman*
T. D. Williamson, *Secretary*
W. S. Baugh
W. C. Dreyer
W. H. Elliot
J. B. Ford
L. T. Gibbs
F. A. Graham
C. F. Guinn
A. N. Horne
J. K. McGoldrick
J. M. McGregor
J. B. McMahon
R. L. Middleton
O. L. Olsen
William Parkerson
W. R. Reed
F. A. Stivers
W. H. Stueve
Fred Thilenius
J. B. Thomas
F. E. Warterfield
Oscar Wolf

WIRE ROPE

Approved by Council January, 1931, to investigate existing rope so that it may be better understood and more effectively used

W. H. Fulweiler, *Chairman*
H. LeR. Brink
D. L. Lindquist
G. W. Martin
C. A. McCune
A. H. McDougall
B. V. E. Nordberg, Jr.
W. S. Paine
W. J. Ryan
George Simpson
L. E. Young

PRIME MOVERS FOR ROTARY DRILLING OF OIL WELLS

Approved by Council January, 1931, to investigate existing types of prime movers used for rotary drilling of oil wells as to their relative efficiencies, costs of operation, and general satisfaction

D. L. Trax, *Chairman*
Raymond Carr
W. H. Carson
R. R. Hawkins
H. W. Manley

CRITICAL PRESSURE STEAM BOILERS

Appointed June, 1931, to study the characteristics of high-pressure forced-circulation steam-generating units

A. A. Potter, *Chairman*
W. H. Armacost
A. D. Bailey
E. G. Bailey
A. G. Christie
F. S. Clark
C. H. Fellows
H. J. Kerr
M. W. Link
G. A. Orrok
H. L. Solberg
P. W. Thompson

SAMPLING PULVERIZED FUEL IN A MOVING GAS STREAM

Appointed November, 1932, to investigate the present methods of sampling pulverized fuel and to evolve a generally satisfactory method that may be adopted as a standard

K. M. Irwin, *Chairman*
F. M. Gibson, *Secretary*
John Blizard
Ollison Craig
M. D. Engle
C. S. Gladden
A. E. Grunert
R. M. Hardgrove
J. C. Hardigg
H. J. Klotz
Henry Kreisinger
J. W. MacKenzie
W. S. Morrison
G. B. Randall
R. C. Roe
E. H. Tenney

COTTON SEED PROCESSING

Appointed December, 1932, to study the mechanical problems involved in storing, conditioning, and cooking cotton seed meats

W. R. Woolrich, *Chairman*
Homer Barnes
E. L. Carpenter
C. E. Garner
B. J. Sams
R. B. Taylor

A.S.M.E. Representatives on Other Research Committees

See also A.S.M.E. Representatives on Other Activities, page RI-29

CORROSION COMMITTEE

American Society of Refrigerating Engineers
(To be appointed)

FATIGUE PHENOMENA OF METALS

American Society for Testing Materials
W. R. Webster

HEAT-TREATMENT OF ROCK DRILL STEELS

Advisory Board of the Bureau of Standards and Bureau of Mines
(To be appointed)

HIGHWAY RESEARCH

Advisory Board of National Research Council
J. G. Bergquist

NATIONAL COMMITTEE ON WOOD UTILIZATION

Department of Commerce, National Bureau of Standards
A. E. Hall

NON-FERROUS METALS AND ALLOYS

Advisory Committee to the National Bureau of Standards
C. H. Bierbaum

PROPERTIES OF REFRACTORY MATERIALS

Advisory Committee to the National Bureau of Standards
E. B. Powell

WATER FOR INDUSTRIAL USES

American Society for Testing Materials
G. D. Bearce

Standardization Technical Committees

(*Personnel of Standing Committee, p.* RI-2)

STANDARDIZATION AND UNIFICATION OF SCREW THREADS (B-1)

* *Joint sponsorship with the Society of Automotive Engineers. Sectional Committee originally organized in June, 1921. Reorganized in February, 1929*

A.S.M.E. Members (Total personnel, 41)

† R. E. Flanders, *Chairman*
Earle Buckingham, *Secretary*
E. J. Bryant
G. S. Case
T. G. Crawford
C. G. Holmberg
† A. M. Houser
H. C. E. Meyer
† P. V. Miller
R. H. Perry
O. B. Zimmerman

Subcommittee Chairmen

No. 1 on Scope, Arrangement and Editing of American National Standard, R. E. Flanders
No. 2 on Terminology and Thread Specifications, Except Gages, C. W. Bettcher
No. 3 on Special Threads and Twelve Pitch Series, Except Gages.
No. 4 on Acme and Other Similar Threads, Except Gages, E. Buckingham
No. 5 on Screw Thread Gages and Inspection, G. S. Case
No. 7 on Wood Screws, A. Boor

PIPE THREADS (B-2)

* *Joint sponsorship with the American Gas Association. Sectional Committee reorganized May, 1927*

A.S.M.E. Members (Total personnel, 48)

A. S. Miller, *Chairman*
A. F. Breitenstein
E. J. Bryant
E. S. Cornell, Jr.
J. J. Crotty
A. P. Denton
J. J. Harman
† A. M. Houser
F. B. Howell
A. H. Jarecki
J. O. Johnson
W. R. Kremer
P. V. Miller
F. H. Morehead
W. C. Morris
S. F. Newman
E. S. Sanderson
L. N. Shannon
W. D. Sizer
J. H. Williams

Subcommittee Chairmen

No. 1 on Editing and Gaging, A. M. Houser
No. 2 on Taper Pipe Threads, S. B. Terry
No. 3 on Straight Pipe Threads, A. S. Miller
No. 4 on Plumbers' Threads, A. F. Breitenstein
No. 5 on Screw Threads for Rigid Steel Conduit, James Barton
No. 6 on Special Threads for Thin Tubes, C. C. Winter

BALL AND ROLLER BEARINGS (B-3)

* *Joint sponsorship with the Society of Automotive Engineers. Sectional Committee organized December, 1920*

A.S.M.E. Members (Total personnel, 19)

† W. P. Kennedy, *Vice-Chairman*
† G. R. Bott
L. A. Cummings
F. G. Hughes
† G. E. Hulse
L. F. Nenninger
† A. E. Norton
Ernest Wooler

Subcommittee Chairman

Annular Ball Bearing, G. R. Bott

ALLOWANCES AND TOLERANCES FOR CYLINDRICAL PARTS AND LIMIT GAGES (B-4)

* *Sole sponsorship. Sectional Committee originally organized in June, 1920. Reorganized in September, 1930*

A.S.M.E. Members (Total personnel, 49)

F. E. Banfield, Jr.
(E. E. Blake, *Alternate*)
F. S. Blackall, Jr.
E. J. Bryant
† Earle Buckingham
† F. H. Colvin
R. E. W. Harrison
F. O. Hoagland
N. E. Jacobi
William Jetter
H. C. E. Meyer
P. V. Miller
W. C. Mueller
† E. C. Peck
W. C. Schoenfeldt
C. C. Stevens
O. B. Zimmerman

Subcommittee Chairman

No. 1 on Tolerance Systems, R. E. W. Harrison

* *Note:* All of the Standards Committees for which the Society is Sponsor or Joint Sponsor are organized under the procedure of the American Standards Association.

† Official A.S.M.E. representatives serving on this committee.

SMALL TOOLS AND MACHINE TOOL ELEMENTS (B-5)

* *Joint sponsorship with the National Machine Tool Builders Association and the Society of Automotive Engineers. Sectional Committee organized September, 1922*

A.S.M.E. Members (Total personnel, 26)

C. W. Spicer, *Chairman*
F. O. Hoagland, *Vice-Chairman*
J. B. Armitage
F. S. Blackall, Jr.
O. W. Boston
E. J. Bryant
Earle Buckingham
† F. H. Colvin
S. A. Einstein
† H. E. Harris
John Haydock
J. E. Lovely
† Simon MacKay
† W. C. Mueller
† E. R. Norris
Erik Oberg

Technical Committee No. 1 on T-Slots

A.S.M.E. Members (Total personnel, 11)

Erik Oberg, *Chairman*
J. B. Armitage
E. P. Burrell
† Harry Cadwallader, Jr.
Herman Casler
S. A. Einstein
R. T. Hazelton
† F. O. Hoagland
† E. R. Norris

Technical Committee No. 2 on Tool Posts and Shanks

A.S.M.E. Members (Total personnel, 9)

O. W. Boston, *Chairman*
F. S. Blackall, Jr.
† Granger Davenport
M. E. Lange

Technical Committee No. 3 on Machine Tapers

A.S.M.E. Members (Total personnel, 21)

F. S. Blackall, Jr., *Chairman*
J. B. Armitage
† E. J. Bryant
† Earle Buckingham
F. H. Colvin
J. B. Dillard
B. P. Graves
H. E. Harris
† F. O. Hoagland
J. H. Horigan
A. H. Lyon
L. F. Nenninger
E. J. Prindle
C. W. Spicer

SUBGROUP CHAIRMEN

Taper Series, F. S. Walters
Steep Taper Series, W. A. Timm
Dimensions, Tolerances and Gages, A. H. Lyon

Technical Committee No. 4 on Spindle Noses and Collets for Machine Tools

A.S.M.E. Members (Total personnel, 26)

J. E. Lovely, *Chairman*
L. F. Nenninger, *Secretary*
J. B. Armitage
B. P. Graves
F. O. Hoagland
A. M. Johnson
M. E. Lange
A. H. Lyon
J. H. Mansfield
H. W. Ruppel
L. D. Spence

SUBGROUP CHAIRMEN

No. 1 on Milling Machines, Small and Medium, J. B. Armitage
No. 2 on Large Milling Machines, A. H. Lyon
No. 3 on Grinding Machine Spindles, H. J. Griffing
No. 4 on Cutting Off Machines, W. H. Welch
No. 5 on Drilling Machines and Horizontal Boring Machines, W. A. Timm
No. 6 on Turning Machines, Including Automatic Screw Machines, Lathes, Automatic Lathes, Turret Lathes, and Automatic Chucking Machines, J. E. Lovely
No. 7 on Cutting and Hobbing Machines, A. L. Stewart
No. 8 on Correlation of Counter Proposals for Spindle Noses, J. E. Lovely

Technical Committee No. 5 on Milling Cutters

A.S.M.E. Members (Total personnel, 21)

J. B. Armitage
† A. N. Goddard
J. H. Horigan
G. L. Markland, Jr.
E. K. Morgan
† Erik Oberg
C. J. Oxford
E. D. Vancil

SUBGROUP CHAIRMEN

No. 1 on Profile Cutters, E. C. Vancil
No. 2 on Keyways, J. B. Armitage
No. 3 on Nomenclature, A. C. Danekind
No. 4 on Limits, J. H. Horigan
No. 5 on Formed Cutters, H. C. Hungerford
No. 6 on Hobs
No. 7 on Inserted Tooth Cutters, J. B. Armitage

Technical Committee No. 6 on Designations and Working Ranges of Machine Tools

A.S.M.E. Members (Total personnel, 19)

John Haydock, *Chairman*
Earle Buckingham
T. H. Doan, Jr.
B. P. Graves
J. J. McBride
E. R. Smith

Technical Committee No. 7 on Twist Drill Sizes

A.S.M.E. Members (Total personnel, 7)

W. C. Mueller, *Chairman*
J. H. Horigan
C. W. Spicer

Technical Committee No. 8 on Jig Bushings

A.S.M.E. Members (Total personnel, 8)

C. R. Alden, *Secretary*
J. H. Horigan
W. C. Mueller
C. J. Oxford
H. E. Wells

SUBGROUP CHAIRMAN

Liner Outer Diameters and Tolerances, W. C. Mueller

Technical Committee No. 9 on Punch Press Tools

A.S.M.E. Members (Total personnel, 16)

D. H. Chason
N. W. Dorman
H. E. Harris
W. C. Mueller
H. E. Wells

Technical Committee No. 10 on Circular Forming Tools and Holders

A.S.M.E. Members (Total personnel, 9)

W. C. Mueller, *Chairman*
William Hartman
L. D. Spence
H. E. Wells

Technical Committee No. 11 on Chucks and Chuck Jaws

A.S.M.E. Member (Total personnel, 9)

J. E. Lovely, *Chairman*

SUBGROUP CHAIRMAN

No. 1 on Master Chuck Jaws, J. E. Lovely
No. 2 on Adapters for Air Cylinders, J. E. Lovely

Technical Committee No. 12 on Cut and Ground Thread Taps

A.S.M.E. Member (Total personnel, 7)

W. C. Mueller

Technical Committee No. 13 on Splines and Splined Shafts

A.S.M.E. Members (Total personnel, 15)

C. W. Spicer, *Chairman*
J. B. Armitage
W. F. Groene
R. E. W. Harrison
F. O. Hoagland
J. E. Lovely
B. F. Waterman

SUBGROUP CHAIRMEN

Machine Tool Splines, R. E. W. HARRISON
Automotive Splines, W. L. BARTH
Involute Splines, P. L. TENNEY

TECHNICAL COMMITTEE NO. 14 ON ELECTRIC WELDING DIES AND ELECTRODE HOLDERS

A.S.M.E. Members (Total personnel, 14)

R. B. LINCOLN
N. McD. LONEY

TECHNICAL COMMITTEE NO. 16 ON ROTATING TOOL SHANKS

A.S.M.E. Members (Total personnel, 20)

E. J. BRYANT, *Chairman*
J. H. HORIGAN, *Secretary*
J. B. DILLARD
E. W. HOWE
W. C. MUELLER
C. J. OXFORD
H. E. WELLS

TECHNICAL COMMITTEE NO. 17 ON NOMENCLATURE FOR SMALL TOOLS AND MACHINE TOOL ELEMENTS

A.S.M.E. Members (Total personnel, 15)

O. W. BOSTON, *Chairman*
F. S. BLACKALL, JR.
F. H. COLVIN
H. E. HARRIS
F. O. HOAGLAND

Ex-Officio Members

C. R. ALDEN
B. P. GRAVES
A. N. GODDARD
C. J. OXFORD
C. W. SPICER
H. E. WELLS

TECHNICAL COMMITTEE NO. 18 ON MULTIPLE SPINDLE DRILLING HEADS

A.S.M.E. Member (Total personnel, 9)

H. E. WELLS

TECHNICAL COMMITTEE NO. 19 ON SINGLE POINT CUTTING TOOLS

A.S.M.E. Members (Total personnel, 2)

F. H. COLVIN, *Chairman*
O. W. BOSTON, *Secretary*

TECHNICAL COMMITTEE NO. 20 ON REAMERS

(Committee being formed)

GEARS (B-6)

** Joint sponsorship with the American Gear Manufacturers Association.*
Sectional Committee organized June, 1921

A.S.M.E. Members (Total personnel, 32)

B. F. WATERMAN, *Chairman*
† EARLE BUCKINGHAM, *Vice-Chairman*
G. H. ACKER
L. H. FRY
C. B. HAMILTON, JR.
D. T. HAMILTON
† O. A. LEUTWILER
G. L. MARKLAND, JR.
H. E. VEHSLAGE

SUBCOMMITTEE CHAIRMEN

No. 1 on Program, B. F. WATERMAN
No. 2 on Editing Reports, B. F. WATERMAN
No. 3 on Nomenclature, D. T. HAMILTON
No. 4 on Tooth Form (Spur Gears), U. S. EBERHARDT
No. 5 on Helical Gears, W. P. SCHMITTER
No. 6 on Worm Gears, T. R. RIDEOUT
No. 7 on Bevel Gears, F. E. McMULLEN
No. 8 on Materials, C. B. HAMILTON, JR.
No. 9 on Inspection, J. P. BREUER
No. 10 on Horse Power Rating, E. BUCKINGHAM

PIPE FLANGES AND FITTINGS (B-16)

** Joint sponsorship with the Heating, Piping, and Air Conditioning Contractors National Association and the Manufacturers Standardization Society of the Valve and Fittings Industry. Sectional Committee organized October, 1921*

A.S.M.E. Members (Total personnel, 55)

† C. P. BLISS, *Chairman*
J. J. HARMAN, *Secretary*
† LESTER BENOIT
A. L. BROWN
W. R. CONARD
SABIN CROCKER
FERDINAND FINK
H. E. HALLER
J. S. HESS
FRANCIS HODGKINSON
† H. A. HOFFER
A. M. HOUSER
D. S. JACOBUS
L. H. JENKS
JOHN KNICKERBACKER
M. B. MACNEILLE
F. H. MOREHEAD
† E. L. MORELAND
† W. S. MORRISON
L. S. MORSE
A. L. PENNIMAN, JR.
WALTER SAMANS
† J. R. TANNER
J. H. TAYLOR
H. L. UNDERHILL
G. W. WATTS
J. H. WILLIAMS

SUBCOMMITTEE CHAIRMEN

No. 1 on Cast Iron Flanges and Flanged Fittings, A. M. HOUSER
No. 2 on Screwed Fittings, F. H. MOREHEAD
No. 3 on Steel Flanges and Flanged Fittings, C. P. BLISS
No. 4 on Materials and Stresses, A. M. HOUSER
No. 5 on Face to Face Dimensions of Ferrous Flanged Valves, J. R. TANNER
No. 6 on Malleable Iron or Steel Brass Seat Unions, C. P. BLISS
No. 7 on Rating of Pipe Fittings, H. C. HEATON
No. 8 on Marking of Pipe Fittings, W. S. MORRISON
No. 9 on Port Openings, W. W. HUBBARD

SHAFTING (B-17)

** Sole sponsorship. Organized October, 1918*

A.S.M.E. Members (Total personnel, 15)

† C. M. CHAPMAN, *Chairman*
† A. A. ADLER
E. E. GREVE
H. C. E. MEYER
L. C. MORROW
C. W. SPICER
† G. N. VAN DERHOEF
† L. W. WILLIAMS

SUBCOMMITTEE CHAIRMEN

No. 1 on Shafting Dimensions, L. W. WILLIAMS
No. 2 on Stock Key Sizes
No. 3 on Code for Design of Transmission Shafting
No. 4 on Taper Keys, J. E. BUSHNELL
No. 5 on Woodruff Keys, L. C. MORROW

BOLT, NUT AND RIVET PROPORTIONS (B-18)

** Joint sponsorship with the Society of Automotive Engineers. Sectional Committee organized March, 1922*

A.S.M.E. Members (Total personnel, 57)

† A. E. NORTON, *Chairman*
H. E. ALDRICH
F. C. BILLINGS
B. G. BRAINE
(D. L. BRAINE, *Alternate*)
ELLWOOD BURDSALL
G. S. CASE
T. G. CRAWFORD
H. P. FREAR
HERMAN KOESTER
S. F. NEWMAN
R. J. WHELAN
E. M. WHITING
V. R. WILLOUGHBY
(J. J. McBRIDE, *Alternate*)
O. B. ZIMMERMAN

SUBCOMMITTEE CHAIRMEN

No. 1 on Large and Small Rivets, E. L. COCHRANE
No. 2 on Wrench Head Bolts and Nuts, T. D. RUDDOCK
No. 3 on Slotted Head Proportions, E. W. REED
No. 4 on Track Bolts and Nuts, C. W. SQUIER
No. 5 on Round Unslotted Head Bolts (Carriage Bolts)
No. 6 on Plow Bolts, O. B. ZIMMERMAN
No. 7 on Body Dimensions and Materials
No. 8 on Nomenclature, G. S. CASE
No. 9 on Socket Head Cap and Set Screws, H. KOESTER

PLAIN AND LOCK WASHERS (B-27)

* *Joint sponsorship with the Society of Automotive Engineers. Sectional Committee organized August, 1925*

A.S.M.E. Members (Total personnel, 40)

Eugene Caldwell
T. G. Crawford
† B. S. Lewis
C. H. Loutrel
J. J. McBride
H. C. E. Meyer
E. H. Waring
E. M. Whiting
O. B. Zimmerman

Subcommittee Chairmen

No. 1 on Plain Washers
No. 2 on Lock Washers, C. H. Loutrel

TRANSMISSION CHAINS AND SPROCKETS (B-29)

* *Joint sponsorship with the Society of Automotive Engineers and the American Gear Manufacturers Association. Sectional Committee organized September, 1917. Reorganized December, 1926*

A.S.M.E. Members (Total personnel, 15)

† F. V. Hetzel, *Chairman*
W. J. Belcher
Joseph Joy
† L. V. Ludy
† E. B. Nichols
D. B. Perry
G. A. Young
O. B. Zimmerman

CODE FOR PRESSURE PIPING (B-31)

* *Sole sponsorship. Sectional Committee organized March, 1926*

A.S.M.E. Members (Total personnel, 89)

E. B. Ricketts, *Chairman*
R. E. Bryant
G. S. Coffin
H. C. Cooper
Sabin Crocker
(J. H. Walker, *Alternate*)
H. D. Edwards
C. A. Ellis
Charles Fitzgerald
W. M. Graff
O. S. Hagerman
H. E. Haller
J. J. Harman
J. S. Haug
(E. B. Severs, *Alternate*)
J. S. Hess
H. A. Hoffer
G. G. Hollins
† A. M. Houser
† Alfred Iddles
J. H. Lawrence
Edward Lenz

C. G. Spencer
J. R. Tanner
J. H. Vance
H. L. Whittemore
J. H. Williams
T. F. Wolfe
G. H. Woodroffe

Subcommittee Chairmen

No. 1 on Plan and Scope and Editing, Sabin Crocker
No. 2 on Power Piping, J. H. Lawrence
No. 3 on Hydraulic Piping
No. 4 on Gas and Air Piping, Alfred Iddles
No. 5 on Refrigerating Piping, A. H. Baer
No. 6 on Oil Piping
No. 7 on Piping Materials and Identification
No. 8 on Fabrication Details, C. G. Spencer
No. 9 on Code for District Heating Piping, D. S. Boyden

WIRE AND SHEET METAL GAGING SYSTEMS (B-32)

* *Joint sponsorship with the Society of Automotive Engineers. Sectional Committee organized November, 1927*

A.S.M.E. Members (Total personnel, 28)

† F. W. Holland
J. F. Howe

Subcommittee Chairmen

No. 1 on Flat Stocks
No. 2 on Wires and Rods, E. E. Rose
No. 3 on Tubing, Piping, Conduit and Casing, F. H. Nullmeyer

SCREW THREADS FOR HOSE COUPLINGS (B-33)

* *Sole sponsorship. Sectional Committee organized August, 1928*

A.S.M.E. Members (Total personnel, 28)

A. L. Brown, *Secretary*
† A. F. Breitenstein
W. L. Curtiss
† W. E. Dunham
J. J. Harman
(F. C. Ernst, *Alternate*)
A. M. Houser
H. C. E. Meyer
J. H. Williams

Subcommittee Chairmen

No. 1 to Draft Recommended Specifications, J. H. Howland
No. 2 on Basic Thread Dimensions, D. R. Miller

WROUGHT IRON AND WROUGHT STEEL PIPE AND TUBING (B-36)

* *Joint sponsorship with the American Society for Testing Materials. Sectional Committee organized April, 1928*

A.S.M.E. Members (Total personnel, 45)

H. H. Morgan, *Chairman*
Sabin Crocker, *Secretary*
H. E. Aldrich
J. B. Aston
L. D. Burritt
† A. M. Houser
† D. S. Jacobus
† (F. S. Clark, *Alternate*)
H. C. E. Meyer
F. H. Morehead
C. W. Mowry
† H. B. Oatley
A. L. Penniman, Jr.
(A. B. Morgan, *Alternate*)
F. N. Speller
J. R. Tanner
A. E. White
H. LeR. Whitney
G. H. Woodroffe

Subcommittee Chairmen

No. 1 on Plan, Scope and Editing, H. H. Morgan
No. 2 on Pipe and Tubing for Low Temperature Service, J. J. Shuman
No. 3 on Pipe and Tubing for High Temperature Service, J. R. Tanner
No. 4 on Materials, F. H. Morehead

PRESSURE AND VACUUM GAGES (B-40)

* *Sole sponsorship. Sectional Committee organized July, 1930*

A.S.M.E. Members (Total personnel 46)

M. D. Engle, *Chairman*
† A. W. Lenderoth, *Secretary*
E. J. Bryant
† J. P. Cavanaugh
Paul Diserens
W. F. Jones
R. J. Kehl
† J. C. McCune
A. H. Morgan
† S. A. Moss
H. B. Reynolds
C. Z. Rosencrans
W. C. Schoenfeldt

Subcommittee Chairmen

No. 1 on Plan and Scope, M. D. Engle
No. 2 on Definitions, C. F. Schwep
No. 3 on Gage Sizes and Mounting Dimensions, H. B. Reynolds
No. 4 on Accuracy and Test Methods, O. J. Hodge

STOCK SIZES, SHAPES AND LENGTHS FOR HOT AND COLD FINISHED IRON AND STEEL BARS (B-41)

* *Sole sponsorship. Sectional Committee organized April, 1929*

A.S.M.E. Members (Total personnel, 27)

J. B. Aston
F. H. Dechant
† L. W. Williams
G. H. Woodroffe
O. B. Zimmerman

Subcommittee Chairmen

No. 1 on Hot Rolled Steel, H. Wysor
No. 2 on Cold Finished Steels, L. E. Creighton
No. 3 on Hot Rolled Iron, G. H. Woodroffe

SPECIFICATIONS FOR LEATHER BELTING (B-42)

** Sole sponsorship. Sectional Committee organized February, 1931*

A.S.M.E. Members (Total personnel, 27)

H. T. Coates
†R. W. Drake
King Hathaway
G. A. Schieren
†C. O. Streeter
O. B. Zimmerman

Subcommittee Chairmen

No. 1 on Standard Specifications, R. C. Bowker
No. 2 on Recommendations for Selection, Care and Installation, G. A. Schieren

MACHINE PINS (B-43)

** Joint sponsorship with the Society of Automotive Engineers. Sectional Committee organized, March, 1926*

A.S.M.E. Members (Total personnel, 18)

†M. E. Steczynski, *Chairman*
†E. J. Bryant
J. J. McBride
H. C. E. Meyer
O. B. Zimmerman

Subcommittees

No. 1 on Straight, Taper and Dowel Pins
No. 2 on Split Pins

FOUNDRY EQUIPMENT AND SUPPLIES (B-45)

** Joint sponsorship with the American Foundrymen's Association. Sectional Committee organized February, 1931*

A.S.M.E. Members (Total personnel, 25)

E. S. Carman, *Chairman*
E. W. Ely
†F. W. Herendeen
(F. B. Howell, *Alternate*)
G. F. Jenks
A. S. Phelps
†H. P. Van Cleve
O. B. Zimmerman

Subcommittee Chairmen

No. 1, L. M. Sherwin
No. 2, E. S. Carman
No. 3, A. S. Phelps

CLASSIFICATION AND DESIGNATION OF SURFACE QUALITIES (B-46)

** Joint sponsorship with the Society of Automotive Engineers. Sectional Committee organized May, 1932*

A.S.M.E. Members (Total personnel, 62)

E. J. Bryant
John Cetrule
T. G. Crawford
†R. C. Deale
U. S. Eberhardt
S. A. Einstein
R. F. Gagg
J. J. Harman
†R. E. W. Harrison
F. V. Hartman
F. O. Hoagland
H. J. Holtzclaw
R. T. Kent
A. H. Lyon
M. J. Reed
F. C. Spencer
C. C. Stevens
J. S. Tawresey
J. R. Weaver
C. H. Whitaker
Ernest Wooler

Subcommittee Chairmen

No. 1 on Surfaces Produced by Tools and Abrasives, J. Cetrule
No. 2 on Surfaces Produced by Molds, Dies, Rolls or Any Other Means of Deforming Materials
No. 3 on Coated Surfaces, G. B. Hogaboom
No. 4 on Symbols for Indicating Surface Quality on Drawings, T. G. Crawford
No. 5 on Ways, Means and Apparatus for Measuring Quality of Surface, J. R. Weaver
No. 6 on Finance, R. E. W. Harrison

COMBUSTION SPACE FOR SOLID FUELS (B-50)

** Sole sponsorship. Sectional Committee organized June, 1933*

A.S.M.E. Members (Total personnel, 21)

C. E. Bronson, *Chairman*
W. G. Christy
John Hunter
A. J. Johnson
†V. G. Leach
T. A. Marsh
J. F. McIntire
R. H. Rowland
†John Van Brunt

Subcommittee Chairmen

No. 1 on Purpose and Scope, C. E. Bronson
No. 2 on Combustion and Design, T. A. Marsh
No. 3 on Warm Air Furnaces
No. 4 on Steel Heating Boilers, W. B. Russell
No. 5 on Cast Iron Boilers, J. F. McIntire

SCHEME FOR IDENTIFICATION OF PIPING SYSTEMS (A-13)

** Joint sponsorship with the National Safety Council. Sectional Committee organized June, 1922*

A.S.M.E. Members (Total personnel, 37)

W. L. Bunker
Crosby Field
Willis Lawrence
†W. S. Morrison
A. K. Ohmes
A. L. Penniman, Jr.
H. S. Smith
F. N. Speller

Subcommittee Chairmen

Identification by Colors, F. P. Ingalls
Classification, C. Field
Identification Markings Other Than Color, W. S. Morrison

MINIMUM REQUIREMENTS FOR PLUMBING AND STANDARDIZATION OF PLUMBING EQUIPMENT (A-40)

** Joint sponsorship with the American Society of Sanitary Engineering. Sectional Committee organized August, 1928*

A.S.M.E. Members (Total personnel, 47)

J. J. Crotty
J. F. Carney
O. E. Goldschmidt
A. M. Houser
G. W. Martin
(A. H. Morgan, *Alternate*)
†W. R. Webster

Subcommittee Chairmen

No. 1 on Minimum Requirements for Plumbing, W. C. Groeniger
No. 2 on Staple Vitreous China Plumbing Fixtures, E. S. Aitkin
No. 3 on Staple Porcelain (All Clay) Plumbing Equipment, E. S.
No. 4 on Enameled Sanitary Ware, A. H. Cline, Jr.
No. 5 on Traps, A. R. McGonegal
No. 6 on Brass Plumbing Products, J. L. Murphy
No. 7 on Brass Fittings for Flared Copper Tubes, F. L. Riggin
No. 8 on Cast Iron Soil Pipe and Fittings, J. J. Crotty
No. 9 on Gasoline, Oil and Grease Separators, J. J. Crotty
No. 10 on Threaded Cast Iron Pipe and Fittings for Drainage and Pressure Purposes
No. 11 on Soldered Fittings for Tubing, A. M. Houser

ELECTRIC MOTOR FRAME DIMENSIONS (C-28)

* *Joint sponsorship with the National Electrical Manufacturers Association. Sectional Committee organized November, 1927*

A.S.M.E. Members (Total personnel, 32)

C. A. Adams
S. A. Einstein
E. W. Ely
F. S. English
W. F. Jones
A. L. McHugh
P. G. Rhoads
† A. G. Trumbull
† E. H. Waring

ROLLED THREADS FOR SCREW SHELLS OF ELECTRIC SOCKETS AND LAMP BASES (C-44)

* *Joint sponsorship with the National Electrical Manufacturers Association. Sectional Committee organized March, 1929*

A.S.M.E. Members (Total personnel, 18)

† E. J. Bryant
† Earle Buckingham
A. B. Morgan
† E. S. Sanderson

LETTER SYMBOLS AND ABBREVIATIONS FOR SCIENCE AND ENGINEERING (Z-10)

* *Joint sponsorship with the A.A.A.S., A.I.E.E., A.S.C.E., S.P.E.E. Sectional Committee organized January, 1926. Reorganized October, 1935*

A.S.M.E. Members (Total personnel, 36)

S. A. Moss, *Vice-Chairman*
R. M. Anderson
E. P. Warner, *Alternate*
K. H. Condit
† R. J. S. Pigott
† S. R. Beitler, *Alternate*

Subcommittee Chairmen

No. 1 on Letter Symbols and Signs for Mathematics, A. A. Bennett
No. 2 on Symbols for Physics and Mechanics, R. E. Peterson
No. 3 on Symbols for Structural Analysis, Albert Haertlein
No. 4 on Symbols for Hydraulics, J. C. Stevens
No. 5 on Symbols for Heat and Thermodynamics, S. A. Moss
No. 6 on Symbols for Photometry and Illumination, E. C. Crittenden
No. 7 on Aeronautical Symbols
No. 8 on Symbols for Electric and Magnetic Quantities, J. F. Meyer
No. 9 on Symbols for Radio
No. 10 on Abbreviations for Engineering and Scientific Terms, G. A. Stetson

DRAWINGS AND DRAFTING ROOM PRACTICE (Z-14)

* *Joint sponsorship with the Society for the Promotion of Engineering Education, Sectional Committee organized July, 1926*

A.S.M.E. Members (Total personnel, 53)

F. DeR. Furman, *Chairman*
C. W. Keuffel, *Secretary*
C. E. Coolidge
T. G. Crawford
H. C. Fletcher
T. E. French
A. C. Harper
E. R. Hill
A. M. Houser
Alfred Iddles
† Samuel Ketchum
F. R. Laney
H. B. Langille
Rudolph Michel
F. W. Ming
E. B. Neil
J. W. Owens
F. C. Panuska
† E. S. Smith, Jr.

Subcommittee Chairmen

No. 1 on Specifications for Paper and Cloth, A. A. Coburn
No. 2 on Method of Indicating Dimensions
No. 3 on Lettering, T. G. Crawford
No. 4 on Layout, D. Baker
No. 5 on Line Work, S. Ketchum
No. 6 on Graphical Symbols on Drawings, T. E. French
Editing Committee, T. E. French

GRAPHIC PRESENTATION (Z-15)

* *Sole sponsorship. Sectional Committee organized November, 1926*

A.S.M.E. Members (Total personnel, 33)

† G. E. Hagemann, *Secretary*
C. M. Bigelow
Wallace Clark
H. G. Crockett
T. E. French
† D. B. Porter

Subcommittee Chairmen

No. 1 on Plan and Scope
No. 2 on Terminology
No. 3 on Preferred Practice in Graphic Presentation, A. H. Richardson
No. 4 on Engineering and Scientific Graphs, W. A. Shewhart

SPEEDS OF MACHINERY (Z-18)

* *Sole sponsorship. Sectional Committee organized May, 1928*

A.S.M.E. Members (Total personnel, 30)

† C. M. Bigelow
† R. C. Deale
Paul Diserens
F. S. English
D. C. Jackson
H. C. E. Meyer
John Reid
P. G. Rhoads
F. C. Spencer
O. B. Zimmerman

Subcommittee Chairmen

No. 1 on Plan and Scope, A. E. Hall
No. 2 on Questionnaire and Canvass to Industry, F. S. English
No. 3—Special Reviewing Committee

GRAPHICAL SYMBOLS AND ABBREVIATIONS FOR USE ON DRAWINGS (Z-32)

* *Joint sponsorship with American Institute of Electrical Engineers. Sectional Committee organized April, 1936*

A.S.M.E. Members (Total personnel 52)

E. E. Ashley
(John James, *Alternate*)
J. M. Barnes
† T. E. French
D. T. Hamilton
F. W. Holland
(J. J. Harman, *Alternate*)
A. M. Houser
I. J. Karassik
L. L. Munier
J. W. Owens
† F. C. Panuska
T. R. Thomas
T. P. Wright

Subcommittee Chairmen

No. 1 on Symbols for Use in Mechanical Engineering, T. E. French
No. 2 on Symbols for Use in Electrical Engineering, H. W. Samson

---

SHAFT COUPLINGS

Appointed in December, 1928

A.S.M.E. Members (Total personnel, 6)

D. J. McCormack, *Chairman*
R. A. McCarty
H. G. Reist
R. E. B. Sharp

DEVELOPMENT OF APPLICATIONS OF STATISTICS IN ENGINEERING AND MANUFACTURING

Joint sponsorship with the American Society for Testing Materials. Appointed in December, 1929

A.S.M.E. Members (Total personnel, 4)

W. H. Fulweiler
† L. K. Sillcox

STANDARD HEIGHT FOR LOADING PLATFORMS AT FREIGHT TERMINALS AND WAREHOUSES

Joint sponsorship with the Society of Terminal Engineers. Appointed in December, 1931

(Total personnel, 14)

† Official A.S.M.E. representative serving on this committee.

A. S. M. E. Representatives on Miscellaneous Standardization Committees

See also A.S.M.E. Representatives on Other Activities, page RI-29

Power Test Codes Technical Committees

(*Personnel of Standing Committee, p.* RI-2)

(1) GENERAL INSTRUCTIONS

Appointed December, 1918

W. H. Kavanaugh, *Chairman*
A. M. Greene, Jr.
C. F. Hirshfeld
M. C. Stuart

(2) DEFINITIONS AND VALUES

Appointed December, 1918
Reorganized, 1936

R. J. S. Pigott, *Chairman*
L. J. Briggs
W. F. Davidson
S. L. Kerr
A. L. Kimball
L. S. Marks
F. G. Philo
J. C. Smallwood
P. W. Swain
A. C. Wood

(3) FUELS

Appointed December, 1918

W. J. Wohlenberg, *Chairman*
E. G. Bailey
B. L. Boye
L. P. Breckenridge
H. W. Brooks
S. B. Flagg
D. M. Myers
F. G. Philo
G. S. Pope
C. R. Richards
E. B. Ricketts
F. M. Rogers
E. X. Schmidt
Nicholas Stahl
E. N. Trump

(4) STATIONARY STEAM-GENERATING UNITS

Appointed December, 1918

E. R. Fish, *Chairman*
C. U. Savoye, *Secretary*
A. D. Bailey
Alfred Iddles
E. B. Powell
E. B. Ricketts

(5) RECIPROCATING STEAM ENGINES

Appointed December, 1918
Reappointed, 1931

A. G. Christie, *Chairman*
Harte Cooke
K. S. M. Davidson
Herman Diederichs
Henrik Greger
Thomas Hall
J. A. Hunter
H. G. Mueller
B. V. E. Nordberg
J. F. M. Patitz
A. V. Saharoff
A. G. Whitting
J. C. Workman

(6) STEAM TURBINES

Appointed December, 1918

C. H. Berry, *Chairman*
I. E. Moultrop, *Secretary*
O. D. H. Bentley
W. E. Caldwell
A. G. Christie
Hans Dahlstrand
V. M. Frost
A. E. Grunert
Francis Hodgkinson
S. A. Moss
R. O. Muller
T. E. Purcell
C. C. Thomas

(7) RECIPROCATING STEAM-DRIVEN DISPLACEMENT PUMPS

Appointed December, 1918

R. D. Hall, *Chairman*
C. H. Anderson
E. H. Brown
J. N. Chester
J. E. Gibson
G. L. Kollberg
M. B. MacNeille
D. W. Mead
L. A. Quayle

(8) CENTRIFUGAL AND ROTARY PUMPS

Appointed December, 1918
Reorganized, 1936

M. B. MacNeille, *Chairman*
H. E. Beckwith
W. B. Gregory
L. F. Moody
Arvid Peterson
F. H. Rogers
W. C. Rudd
Max Spillman
W. M. White
I. A. Winter

(9) DISPLACEMENT COMPRESSORS AND BLOWERS

Appointed December, 1918
Reorganized, 1935

Paul Diserens, *Chairman*
G. T. Felbeck
J. F. Huvane
R. M. Johnson
J. F. D. Smith

(10) CENTRIFUGAL AND TURBO-COMPRESSORS AND BLOWERS

Appointed December, 1918
Reappointed, 1929

A. T. Brown, *Chairman*
E. L. Anderson
C. A. Booth
W. H. Carrier
Thomas Chester
L. E. Day
E. S. Dean
Z. G. Deutsch
S. H. Downs
P. E. Good
J. J. Grob
H. F. Hagen
Paul Hoffman
H. D. Kelsey
A. L. Kimball
L. S. Marks
Arvid Peterson
H. F. Schmidt
M. C. Stuart

(11) COMPLETE STEAM POWER PLANTS

Appointed December, 1918
Reappointed, 1933

F. M. Van Deventer, *Chairman*
D. S. Wegg, *Secretary*
W. F. Davidson
C. H. Fellows
R. A. Foresman
V. M. Frost
W. W. Johnson
E. W. Norris
H. S. Whiton

(12) CONDENSERS, WATER HEATING, AND COOLING EQUIPMENT

Appointed December, 1918

G. A. Orrok, *Chairman*
P. J. Hardie, *Secretary*
C. H. Baker, Jr.
R. N. Ehrhart
J. F. Grace
D. W. R. Morgan
J. J. Mullan
H. B. Reynolds
P. E. Reynolds

(13) REFRIGERATING SYSTEMS

Appointed December, 1918

G. A. Horne, *Chairman*
G. B. Bright
N. H. Hiller
G. T. Voorhees

(14) EVAPORATING APPARATUS

Appointed December, 1918

E. N. Trump, *Chairman*
B. N. Bump
E. A. Newhall
H. L. Parr
L. C. Rogers

(15) STEAM LOCOMOTIVES

Appointed December, 1918

E. C. Schmidt, *Chairman*
W. F. Kiesel, Jr.
H. B. Oatley
G. E. Rhoads
L. K. Sillcox
W. E. Woodard

(16) GAS PRODUCERS

Appointed December, 1918

R. H. Fernald
C. D. Smith
H. F. Smith

(17) INTERNAL-COMBUSTION ENGINES

Appointed December, 1918
Reappointed, 1928

Max Rotter, *Chairman*
Harte Cooke
L. B. Jackson
B. V. E. Nordberg
J. H. Suter

(18) HYDRAULIC PRIME MOVERS

Appointed December, 1918
Reappointed, 1931

E. C. Hutchinson, *Chairman*
C. M. Allen
H. L. Doolittle
W. F. Durand
N. R. Gibson
J. P. Growdon
T. H. Hogg
D. J. McCormack
L. F. Moody
R. V. Terry
W. M. White

(19) INSTRUMENTS AND APPARATUS

Appointed December, 1918

C. F. Hirshfeld, *Chairman*
W. A. Carter, *Secretary*
C. M. Allen
E. G. Bailey
H. S. Bean
L. J. Briggs
C. R. Cary
J. D. Davis
R. E. Dillon
F. M. Farmer
J. B. Grumbein
W. W. Johnson
W. H. Kenerson
E. S. Lee
E. L. Lindseth
Osborn Monnett
S. A. Moss
R. J. S. Pigott
E. B. Ricketts
W. A. Sloan
R. B. Smith

(20) SPEED-RESPONSIVE GOVERNORS

Appointed December, 1921

Francis Hodgkinson, *Chairman*
Harte Cooke
J. F. M. Patitz
F. H. Rogers

(21) DUST SEPARATING APPARATUS

Appointed October, 1934

M. D. Engle, *Chairman*
Ollison Craig, *Secretary*
E. L. Anderson
A. D. Bailey
H. H. Bubar
W. G. Christy
H. O. Croft
J. M. DallaValle
Philip Drinker
J. W. Fehnel
H. F. Hagen
P. H. Hardie
C. W. Hedberg
J. H. Leech
H. E. Macomber
H. B. Meller
H. C. Murphy
B. F. Tillson

Safety Technical Committees

(*Personnel of Standing Committee, p.* RI-2)

SAFETY CODE FOR MECHANICAL POWER-TRANSMISSION APPARATUS

* *Joint sponsorship with the International Association of Industrial Accident Boards and Commissions, National Bureau of Casualty and Surety Underwriters. Sectional Committee organized February, 1921*

A.S.M.E. Members (Total personnel, 35)

† C. B. Auel, *Chairman*
P. G. Rhoads, *Temporary Secretary*
† L. A. DeBlois
C. C. Foster
(W. M. Graff, *Alternate*)
W. J. Hamilton
† G. M. Naylor
W. W. Nichols
W. S. Paine
† D. C. Wright
(† G. N. VanDerhoef, *Alternate*)

Subcommittee Chairmen

No. 1 on Detail Classification of Belts
No. 2 on Modification of Rule 223 for Cone Pulley Belts
No. 3 on Mechanical Power Control, W. M. Graff
No. 4 on Use of ASA Code versus State Codes, L. A. DeBlois
No. 5 on Statistics on Place of Occurrence of Accidents

SAFETY CODE FOR ELEVATORS

* *Joint Sponsorship with the American Institute of Architects and the National Bureau of Standards. Sectional Committee organized November, 1922*

A.S.M.E. Members (Total personnel, 42)

O. P. Cummings, *Vice-Chairman*
C. R. Callaway
† D. L. Holbrook
† Bassett Jones
D. L. Lindquist
† N. O. Lindstrom
J. J. Matson
J. C. McCabe
M. B. McLauthlin
W. S. Paine

Subcommittee Chairmen

Research, Recommendations and Interpretations, D. J. Purinton
Inspectors' Handbook, K. A. Colahan
Elevator Systems Safe Against Fire, W. S. Paine
Interlocks and Hoistway Enclosures, B. Jones

SAFETY CODE ON COMPRESSED AIR MACHINERY AND EQUIPMENT

* *Joint sponsorship with the American Society of Safety Engineers—Engineering Section, National Safety Council. Sectional Committee organized May, 1923*

A.S.M.E. Members (Total personnel, 25)

D. L. Royer, *Chairman*

SAFETY CODE FOR ABRASIVE WHEELS

** Sponsor bodies: Grinding Wheel Manufacturers Association of United States and Canada, and International Association of Industrial Accident Boards and Commission*

W. B. GARDINER

SAFETY CODE FOR AERONAUTICS

** Sponsor body: Society of Automotive Engineers*

(To be appointed)

SAFETY CODE FOR AMUSEMENT PARKS

** Sponsor bodies: National Association of Amusement Parks, and National Bureau of Casualty and Surety Underwriters*

G. P. SMITH, JR.

SAFETY CODE FOR CONSTRUCTION WORK

** Sponsor bodies: American Institute of Architects and National Safety Council*

(To be appointed)

COOPERATION WITH OTHER ENGINEERING SOCIETIES

Sponsor body: American Society of Safety Engineers

H. L. MINER

A.S.A. SAFETY CODE CORRELATING COMMITTEE

T. A. WALSH, JR. (H. H. JUDSON, *Alternate*)

SAFETY CODE FOR EXHAUST SYSTEMS

** Sponsor body: International Association of Industrial Accident Boards and Commissions*

J. C. HARDIGG (E. H. DECONINGH, *Alternate*)

SAFETY CODE FOR FLOOR AND WALL OPENINGS, RAILINGS, AND TOE BOARDS

** Sponsor body: National Safety Council*

WILLIAM COLLINS

SAFETY CODE FOR FORGING AND HOT METAL STAMPING

** Sponsor bodies: American Drop Forging Institute and National Safety Council*

O. F. LUCKENBACH
C. F. PARK

SAFETY CODE ON COLORS FOR IDENTIFICATION OF GAS MASK CANISTERS

** Sponsor body: National Safety Council*

L. C. LICHTY

SAFETY CODE FOR LADDERS

** Sponsor body: National Safety Council*

W. T. HATCH

SAFETY CODE FOR LAUNDRY MACHINERY AND OPERATION

** Sponsor bodies: Laundry Owners National Association, International Association of Governmental Labor Officials and National Association of Mutual Casualty Companies*

E. J. CARROLL

SAFETY CODE FOR LIGHTING FACTORIES, MILLS, AND OTHER WORKS PLACES

** Sponsor body: Illuminating Engineering Society*

L. A. BLACKBURN

SAFETY CODE FOR LOGGING AND SAWMILL MACHINERY

** Sponsor body: National Bureau of Standards*

J. H. DICKINSON

LOW VOLTAGE ELECTRICAL HAZARD

** Special Committee of the American Society of Safety Engineers—Engineering Section, National Safety Council*

J. P. JACKSON

SAFETY CODE FOR MECHANICAL REFRIGERATION

** Sponsor body: American Society of Refrigerating Engineers*

O. A. ANDERSON
CROSBY FIELD
W. F. JONES
(A. W. OAKLEY, *Alternate to all A.S.M.E. Representatives*)

SAFETY CODE FOR PAPER AND PULP MILLS

** Sponsor body: National Safety Council*

R. L. WELDON

SAFETY CODE FOR POWER PRESSES, AND FOOT AND HAND PRESSES

** Sponsor body: National Safety Council*

E. E. BARNEY

SAFETY CODE FOR PREVENTION OF DUST EXPLOSIONS

** Sponsor bodies: National Fire Protection Association and U. S. Department of Agriculture*

J. H. MORROW
R. M. FERRY

SAFETY CODE FOR PROTECTION OF HEADS, EYES AND RESPIRATORY ORGANS OF INDUSTRIAL WORKERS

** Sponsor body: National Bureau of Standards*

T. A. Walsh, Jr. (T. F. Hatch, *Alternate*)

SAFETY CODE FOR PROTECTION OF INDUSTRIAL WORKERS IN FOUNDRIES

** Sponsor bodies: American Foundrymen's Association and National Founders Association*

H. M. Lane

SAFETY CODE FOR RUBBER MACHINERY

** Sponsor bodies: National Safety Council and International Association of Industrial Accident Boards and Commissions*

(To be appointed)

SPECIFICATIONS AND METHODS OF TEST FOR SAFETY GLASS

** Sponsor bodies: National Bureau of Casualty and Surety Underwriters and National Bureau of Standards*

T. A. Walsh, Jr.

SAFETY CODE FOR TEXTILES

** Sponsor body: National Safety Council*

G. L. Warfield

SAFETY CODE FOR UNDERGROUND POWER TRANSMISSION AND POWER EQUIPMENT FOR METAL MINES

** Sponsor body: American Mining Congress, National Standardization Division*

(To be appointed)

SAFETY CODE FOR VENTILATION

** Sponsor body: American Society of Heating and Ventilating Engineers*

P. A. McKittrick (L. H. Eggert, *Alternate*)

SAFETY CODE FOR WALKWAY SURFACES

** Sponsor bodies: American Institute of Architects and National Safety Council*

W. M. Graff

SAFETY CODE FOR WINDOW WASHING

** Sponsor body: National Safety Council*

W. G. Boyle

SAFETY CODE FOR WORK IN COMPRESSED AIR

** Sponsor body: International Association of Industrial Accident Boards and Commissions*

L. J. Eibsen

WESTERN SOCIETY OF ENGINEERS

WASHINGTON AWARD

O. A. Leutwiler (1937) — C. B. Nolte (1938)

Awards

The following paragraphs deal with the medals, awards, scholarships, and loan funds which come within the jurisdiction of the A.S.M.E. The Society also participates with other engineering societies in a number of joint awards.

Honorary Membership, to which persons of acknowledged professional eminence are elected by unanimous vote of Council under the provisions of the By-Laws and Rules. A list of honorary members is given on page RI-33.

Life Membership, which may be conferred by the Council for distinguished service to the Society; or secured by a member by payment for an annuity in accordance with the provisions of the By-Laws.

A.S.M.E. Medal, established by the Society in 1920 to be presented, together with an engraved certificate, for distinguished service in engineering and science. May be awarded for general service in science having possible application in engineering.

Holley Medal, instituted and endowed in 1924 by George I. Rockwood, Past Vice-President of the Society, to be bestowed, together with an engraved certificate, for some great and unique act of genius of engineering nature that has accomplished a great and timely public benefit.

Worcester Reed Warner Medal, provision for which was made in the will of Worcester Reed Warner, Honorary Member of the Society, is a gold medal to be bestowed, together with an engraved certificate, on the author of the most worthy paper received, dealing with progressive ideas in mechanical engineering or efficiency in management.

Melville Medal, established in 1914 by the bequest of Rear-Admiral George W. Melville, Honorary Member and Past-President of the Society, to be presented, together with an engraved certificate, for an original paper or thesis of exceptional merit, presented to the Society for discussion and publication, to encourage excellence in papers. The medal may be presented annually.

Spirit of Saint Louis Medal, endowed by members of the Society and citizens residing in St. Louis, Mo., to be awarded for meritorious service in the field of aeronautical engineering. This medal will be awarded at the discretion of the Council of the Society at approximately three-year periods upon the recommendation of a Spirit of Saint Louis Medal Board of Award made up of six members, each appointed for a term of nine years and the terms of two members expiring at each three-year period. The St. Louis Section and the Aeronautic Division will each be responsible for the nomination of three members.

Junior Award, annual cash award of $50, established in 1914, from a fund created by Henry Hess, Past Vice-President of the Society, to be presented, together with an engraved certificate, for the best paper or thesis submitted by a Junior Member.

Student Awards, two annual cash awards of $25 each, established in 1914, from a fund created by Henry Hess, Past Vice-President of the Society, to be presented, together with engraved certificates, for the best papers or theses submitted by Student Members. The awards for 1932 and subsequent years have been given, one for undergraduate and the other for postgraduate work.

Charles T. Main Award, annual cash award of $150, established in 1919 from a fund created by Charles T. Main, Past-President of the Society, to be awarded, together with an engraved certificate, to a Student Member of the Society, for the best paper within the general subject of the influence of the profession upon public life. The exact subject is assigned by the Board of Honors and Awards, subject to the approval of the Council, and is announced each year through the Honorary Chairmen of the Student Branches.

SCHOLARSHIPS AND LOAN FUNDS

Max Toltz: Loan Fund of $15,000 established by Major Max Toltz, former member of the Council of the Society, the income to be used for assistance to Student Members.

John R. Freeman: Fund of $25,000 established in 1926 by John R. Freeman, Past-President of the Society, the income to be used for travel scholarships and research.

Woman's Auxiliary: Scholarship or Fellowship offered by the Woman's Auxiliary to the Society to assist sons and daughters of members or worthy students of mechanical engineering.

RECIPIENTS OF AWARDS

The names of the recipients of the different awards to date are given in the following lists, together with the dates of presentation, and the services or papers for which the awards were made. There were no awards for the years not listed.

A.S.M.E. Medal

1921 Hjalmar Gotfried Carlson, in recognition of the services rendered the Government because of his invention and part in the production of 20,000,000 Mark III drawn steel booster casings used principally as a component of 75-mm high-explosive shells, but also used extensively in gas shells and bombs

1922 Frederick Arthur Halsey, for his paper describing the premium system of wage payments presented before the

Society at the Providence Meeting in 1891, as the adoption of the methods there proposed has had a profound effect toward harmonizing the relations of worker and employer

1923 John Ripley Freeman, for his eminent service in engineering and manufacturing by his meritorious work in fire prevention and the preservation of property

1926 R. A. Millikan, in recognition of his contributions to science and engineering

1927 Wilfred Lewis, for his contributions to the design and construction of gear teeth

1928 Julian Kennedy, for his services and contributions to the iron and steel industry

1929 William LeRoy Emmet, for his contributions in the development of the steam turbine, electric propulsion of ships, and other power-generating apparatus

1931 Albert Kingsbury, for his research and development work in the field of lubrication

1933 Ambrose Swasey, for his contributions to the advancement of the engineering profession and for his part in the development of the turret lathe and the astronomical telescope

1934 Willis H. Carrier, in recognition of his research and development work in air-conditioning

1935 Charles T. Main, for distinguished achievements in the textile and other industries, in engineering education, and for eminent service to the engineering profession

1936 Edward Bausch, for meritorious mechanical developments in the field of optics.

Holley Medal

1924 Hjalmar Gotfried Carlson, for his inventions and processes which made possible the timely production of drawn steel booster casings for artillery ammunition, thereby aiding victory in the World War (diploma in recognition of achievements presented in 1921)

1927 Elmer Ambrose Sperry, for achievements and inventions that have advanced the naval arts, including the gyroscope that has freed navigation from the dangers of the fluctuating magnetic compass

1929 Baron Chuzaburo Shiba, for his contributions to knowledge through fundamental research, including the field of aerodynamics, by the development of ultra-rapid kinematographic methods

1934 Irving Langmuir, for his contributions to science and engineering, including the development of gas-filled incandescent lamps, thoriated filament for thermionic emission, atomic hydrogen welding, phase control operation of the thyratron tube, and fundamental research in oil films

1936 Henry Ford, for revolutionary influence through invention and practice on transportation and on mass production methods in manufacturing.

Worcester Reed Warner Medal

1933 Dexter S. Kimball, for his contributions to efficiency in management as exemplified by his recently revised "Principles of Industrial Organization" and by his many articles, engineering society papers, and public addresses

1934 Ralph E. Flanders, for his contributions to a better understanding of the relationship of the engineer to economic problems and social trends as exemplified by the many papers which he has presented

1935 Stephen Timoshenko, for his contributions to the theory of the design of elastic structures and the treatment of dynamics of moving machinery

1936 Charles M. Allen, for his early and continued hydraulic laboratory work and for the permanent value of the papers on his development of methods of testing large hydraulic turbine installations.

Melville Medal

1927 Leon P. Alford, "Laws of Manufacturing Management"

1929 Joseph W. Roe, "Principles of Jig and Fixture Practice"

1930 Herman Diederichs and William D. Pomeroy, "The Occurrence and Elimination of Surge or Oscillating Pressure in Discharge Lines From Reciprocating Pumps"

1931 Arthur E. Grunert, "Comparative Performance of a Pulverized-Coal-Fired Boiler Using Bin System and Unit System of Firing"

1932 Alexey J. Stepanoff, "Leakage Loss and Axial Thrust in Centrifugal Pumps"

1933 William E. Caldwell, "Characteristics of Large Hell Gate Direct-Fired Boiler Units"

1935 Oscar R. Wikander, "Draft-Gear Action in Long Trains"

1936 H. A. Stevens Howarth, for his paper The Loading and Friction of Thrust and Journal Bearings with Perfect Lubrication.

Spirit of Saint Louis Medal

1929 Daniel Guggenheim, founder of the Guggenheim Fund for the Promotion of Aeronautics

1932 Paul Litchfield, for his work in encouraging and sponsoring airship design and construction in this country

1935 Will Rogers, for his splendid, constructive, and unselfish work in the achievement of aviation, and the building up of public confidence in aviation through his articles in the press, over the radio, and from the speaker's platform.

Junior Award

1915 Ernest O. Hickstein, "Flow of Air Through Thin Plate Orifices"

1916 L. M. McMillan, "The Heat Insulating Properties of Commercial Steam-Pipe Coverings"

1919 E. D. Whalen, "Properties of Airplane Fabrics"

1921 S. Logan Kerr, "Moody Ejector Turbine"

1922 R. H. Heilman, "Heat Losses From Bare and Covered Wrought-Iron Pipe at Temperatures Up to 800 Degrees Fahrenheit"

F. L. Kallam, "Preliminary Report on the Investigation of the Thermal Conductivity of Liquids"

1923 S. S. Sanford and S. Crocker, "The Elasticity of Pipe Bends"

1924 R. H. Heilman, "Heat Losses Through Insulating Material"

1925 Gilbert S. Schaller, "An Investigation of Seattle as a Location for a Synthetic Foundry Industry"

1927 Wm. M. Frame, "Stresses Occurring in the Walls of an Elliptical Tank Subjected to Low Internal Pressure"

1928 M. D. Aisenstein, "A New Method of Separating the Hydraulic Losses in a Centrifugal Pump"

1929 Arthur M. Wahl, "Stresses in Heavy, Closely Coiled Helical Springs"

1930 Ed Sinclair Smith, Jr., "Quantity-Rate Fluid Meters"

1931 M. K. Drewry, "Radiant-Superheater Developments"

1932 Edmond M. Wagner, "Frictional Resistance of a Cylinder Rotating in a Viscous Fluid Within a Coaxial Cylinder"

1933 Townsend Tinker, "Surface Condenser Design and Operating Characteristics"

1934 John I. Yellott, Jr., "Supersaturated Steam"

1935 Stanley J. Mikina, "Effect of Skewing and Pole Spacing on Magnetic Noise in Electrical Machinery"

1936 Harwood F. Mullikan, Jr., "Evaluation of Effective Radiant Heating Surface and Application of the Stefan-Boltzman Law to Heat Absorption in Boiler Furnaces."

Student Award

1916 Boynton M. Green, Stanford University, "Bearing Lubrication"

Howard E. Stevens, Rensselaer Polytechnic Institute, "An Investigation of the Dynamic Pressure on Submerged Flat Plates"

M. Adam, Louisiana State University, "The Adaptability of the Internal Combustion Engine to Sugar Factories and Estates"

1917 H. R. Hammond and C. W. Holmberg, Pennsylvania State College, "Study of Surface Resistance With Glass as the Transmission Medium"

1919 C. F. Leh and F. G. Hampton, Stanford University, "An Experimental Investigation of Steel Belting"

W. E. Helmick, Stanford University, "An Experimental Investigation of Steel Belting"

1920 Howard G. Allen, Cornell University, "Wire Stitching Through Paper"

1921 Karl H. White, University of Kansas, "Forces in Rotary Motors"

Richard H. Morris and Albert J. R. Houston, University of California, "A Report Upon an Investigation of the Herschel Type of Improved Weir"

1923 CHARLES F. OLMSTEAD, University of Minnesota, "Oil Burning for Domestic Heating"
H. E. DOOLITTLE, University of California, "The Integrating Gate: A Device for Gaging in Open Channels"
1924 GEORGE STUART CLARK, Stanford University, "Two Methods Used for the Determination of the Gasoline Content of Absorption Oils in Absorption Plants"
L. J. FRANKLIN AND CHARLES H. SMITH, Stanford University, "The Effect of Inaccuracy of Spacing on the Strength of Gear Teeth"
1925 HARRY PEASE COX, JR., Rensselaer Polytechnic Institute, "A Study of the Effect of End Shape on the Towing Resistance of a Barge Model"
W. S. MONTGOMERY, JR., AND E. RAY ENDERS, JR., Pennsylvania State College, "Some Attempts to Measure the Drawing Properties of Metals"
1926 R. E. PETERSON, University of Illinois, "An Investigation of Stress Concentration by Means of Plaster of Paris Specimens"
CECIL G. HEARD, University of Toronto, "Pressure Distribution Over U. S. A. 27 Aerofoil With Square Wing Tips Model Tests"
1927 ALFRED H. MARSHALL, Princeton, "Evaporative Cooling"
ROGER IRMIN EBY, University of Washington, "Measurement of the Angular Displacement of Flywheels"
1928 CLARENCE C. FRANCK, Johns Hopkins University, "Condition Curves and Reheat Factors for Steam Turbines"
1929 FRANK VERNON BISTROM, University of Washington, "An Investigation of a Rotary Pump"
WILLIAM WALLACE WHITE, University of Washington, "An Investigation of a Rotary Pump"
1930 GERARD EDEN CLAUSSEN, Polytechnic Institute of Brooklyn, "High-Temperature Oxidation of Steel"
HAROLD L. ADAMS AND RICHARD L. STITH, University of Washington, "A Wind Tunnel for Undergraduate Laboratory Experiments"
1931 JULES PODNOSSOFF, Polytechnic Institute of Brooklyn, "Pressure and Energy Distribution in Multi-Stage Steam Turbines Operating Under Varying Conditions"
1932 H. E. FOSTER, JR., University of Tennessee, "Factors Affecting Spray Pond Design" (Undergraduate Award)
WILLIAM A. MASON, Stanford University, "An Experimental Investigation of the Flame Propagation in Internal-Combustion Engines" (Postgraduate Award)
1933 HUGO V. CORDIANO, Polytechnic Institute of Brooklyn, "Thermal Analysis of Lithium-Magnesium System of Alloys" (Undergraduate Award)
JAMES A. OSTRAND, JR., Princeton University, "Sudden Enlargement in the Open Channel" (Postgraduate Award)
1934 H. REYNOLDS HUDSON, Georgia School of Technology, "Dynamic Balance and Functional Utility Applied to Automotive Design" (Undergraduate Award)
1935 CHARLES P. BACHA, Rutgers University, "The Behavior of Metals Subjected to Combined Stress" (Postgraduate Award)
ROBERT W. BEAL, Oregon State College, "Do Lubricating Oils Wear Out?" (Undergraduate Award)
1936 LEON B. STINSON, Oklahoma Agricultural and Mechanical College, "Polymerized Motor Fuels; Their Economic Significance" (Undergraduate Award)
DEWITT D. BARLOW, JR., Princeton University, "The Critical Speeds of Lateral Vibrations of Shafts with Gyroscopic Effect" (Postgraduate Award).

CHARLES T. MAIN AWARD

1925 CLEMENT R. BROWN, Catholic University of America. Subject: "The Influence of the Locomotive on the Unity of the United States"
1926 W. C. SAYLOR, Johns Hopkins University. Subject: "The Effect of the Cotton Gin Upon the History of the United States During Its First Seventy Years"
1927 No award. Subject: "Scientific Management and Its Effect Upon the Industries"
1928 ROBERT M. MEYER, Newark College of Engineering. Subject: "Scientific Management and Its Effect Upon Manufacturing"
1929 No award. Subject: "The Influence of Engineering on Farm Production"
1930 JULES PODNOSSOFF, Polytechnic Institute of Brooklyn. Subject: "The Value of the Safety Movement in the Industries"
1931 ROBERT E. KLISE, University of Michigan. Subject: "Interchangeability—Its Development and Significance in Industry"
1932 MARSHALL ANDERSON, University of Michigan. Subject: "Apprenticeship and Vocational Training"
1933 GEORGE D. WILKINSON, JR., Newark College of Engineering. Subject: "Progress in the Prevention of Smoke and Atmospheric Pollution"
1934 PHILIP P. SELF, Colorado State College. "Air Conditioning—Its Practicability and Relation to Public Welfare"
1935 G. LOWELL WILLIAMS, Lafayette College. Subject: "Coordinated Transportation—An Economic Comparison of Railroad, Bus, Truck, Water, and Air Transportation for Long and Short Haul"
1936 No award. Subject: "Development in the Generation and Distribution of Power and Their Effect upon the Consumer."

FREEMAN TRAVEL SCHOLARSHIP

1927 HERBERT N. EATON
1928 BLAKE R. VAN LEER
1929 ROBERT T. KNAPP
1931 REGINALD WHITAKER
1932 G. ROSS LORD
1933, 1934 H. J. CASEY
1935, 1936 VICTOR L. STREETER

1885	Josephus Flavius Holloway (1896)
1886	Coleman Sellers (1907)
1887	George H. Babcock (1893)
1888	Horace See (1909)
1889	Henry Robinson Towne (1924)
1890	Oberlin Smith (1926)
1891	Robert Woolston Hunt (1923)
1892	Charles Harding Loring (1907)
1893–1894	Eckley Brixton Coxe (1895)
1895	Edward F. C. Davis (1895)
1895	Charles Ethan Billings (1920)
1896	John Fritz (1913)
1897	Worcester Reed Warner (1929)
1898	Charles Wallace Hunt (1911)
1899	George Wallace Melville (1912)
1900	Charles Hill Morgan (1911)
1901	Samuel T. Wellman (1919)
1902	Edwin Reynolds (1909)
1903	James Mapes Dodge (1915)
1904	Ambrose Swasey
1905	John Ripley Freeman (1932)
1906	Frederick Winslow Taylor (1915)
1907	Frederick Remsen Hutton (1918)
1908	Minard Lafever Holman (1925)
1909	Jesse Merrick Smith (1927)
1910	George Westinghouse (1914)
1911	Edward Daniel Meier (1914)
1912	Alexander Crombie Humphreys (1927)
1913	William Freeman Myrick Goss (1928)
1914	James Hartness (1934)
1915	John Alfred Brashear (1920)
1916	David Schenck Jacobus
1917	Ira Nelson Hollis (1930)
1918	Charles Thomas Main
1919	Mortimer Elwyn Cooley
1920	Fred J. Miller
1921	Edwin S. Carman
1922	Dexter Simpson Kimball
1923	John Lyle Harrington
1924	Frederick Rollins Low (1936)
1925	William Frederick Durand
1926	William Lamont Abbott
1927	Charles M. Schwab
1928	Alex Dow
1929	Elmer Ambrose Sperry (1930)
1930	Charles Piez (1933)
1931	Roy V. Wright
1932	Conrad N. Lauer
1933	A. A. Potter
1934	Paul Doty
1935	Ralph E. Flanders
1936	William L. Batt

Index to Society Records, Part 1

The page numbers in this section are preceded by the letters "RI," which are omitted in the following index.

INDEX TO COUNTRIES

ALPHABETICAL LIST OF MEMBERS

A

Aarflot, M. G.......New York, N. Y.
Aaron, H. R.................
Singapore, Malay Penin.
Aaron, R. H.....Los Angeles, Calif.
Abadjieff, I. V......Worcester, Mass.
Abbatiello, A. A..Schenectady, N. Y.
Abbe, R. H......Newburyport, Mass.
Abbey, H. G..........New York, N. Y.
Abbott, C. C........Pittsfield, Mass.
Abbott, J., Jr.........Bogota, N. J.
Abbott, R. G.........Anderson, Ind.
Abbott, S................Dallas, Tex.
Abbott, W. G., Jr.....Wilton, N. H.
Abbott, W. L...........Chicago, Ill.
Abdun-Nur, E. A.......Denver, Colo.
Abe, K................Tokyo, Japan
Abe, P. A...............Sidney, Ohio
Abel, C. R...........Camden, N. J.
Abell, H. C.........New Orleans, La.
Abendschein, E. J.Niagara Falls, N. Y.
Abercrombie, J. H......Reigate, Eng.
Abercrombie, W. T., Jr........
Burlington, N. J.
Abcozbeeb, A. E....Cambridge, Mass.
Aborn, G. P...........Waban, Mass.
Abrahamson, E. W.....Buffalo, N. Y.
Abrahamson, W. A....Brooklyn, N. Y.
Abrams, C. ....Newberry, S. C.
Abrams, H. T..........Orange, N. J.
Abrams, V. R.......Elizabeth, N. J.
Acheson, A. R........Syracuse, N. Y.
Acheson, H. A.....Port Huron, Mich.
Acheson, J. M......New York, N. Y.
Ackart, E. G.......Wilmington, Del.
Acker, G. H.........Cleveland, Ohio
Acker, S. H.........Nashville, Tenn.
Ackerman, A. A......Cleveland, Ohio
Ackerman, F..........St. Louis, Mo.
Ackerman, W. L.........Peoria, Ill.
Adair, F. M.........Manhattan, Kan.
Adair, J. G.......Washington, D. C.
Adamaszek, J.........Detroit, Mich.
Adams, A. C.........Cleveland, Ohio
Adams, A. H.......New York, N. Y.
Adams, C. A..........Belmont, Mass.
Adams, C. R............S. Bend, Ind.
Adams, C. S..........Oakland, Calif.
Adams, C. V............Chicago, Ill.
Adams, E. E............Chicago, Ill.
Adams, E. T......Long Beach, Calif.
Adams, F. E.........Berkeley, Calif.
Adams, F. S......Washington, D. C.
Adam, F. W...........Madison, Me.
Adams, H. B., Jr..Bauru, Brazil, S. A.
Adams, H. E......S. Norwalk, Conn.
Adams, H. H............Chicago, Ill.
Adams, H. L...........Seattle, Wash.
Adams, J. E...Elmhurst, L. I., N. Y.
Adams, J. Q......Schenectady, N. Y.
Adams, L. D...........Detroit, Mich.
Adams, O. P.........McKeesport, Pa.
Adams, P. H.........Northfield, Vt.
Adams, S.............Cleveland, Ohio
Adams, W. H..........Hondo, Calif.
Adamson, K.....................
Aberdeen Proving Ground, Md.
Addams, H..........New York, N. Y.
Addicks, L...............Bel Air, Md.
Addicks, M. C.........St. Louis, Mo.
Adelman, A.......Washington, D. C.
Adelson, J. S........Cleveland, Ohio
Adie, J. A...Point Pleasant, W. Va.
Adler, A. A.........Arlington, N. J.
Adolphson, H. B.....Plainfield, N. J.
Adolphson, J. F.......St. Louis, Mo.
Adolphson, R. T.......St. Louis, Mo.
Adolphus, K. B. H.
Montreal, Que., Can.
Adwany, R. K.......Cleveland, Ohio
Adzima, G. R.......Westfield, Mass.
Aeberli, A.......Toronto, Ont., Can.

GEOGRAPHICAL LIST OF MEMBERS

UNITED STATES OF AMERICA

Including Territories and Dependencies

ALABAMA

ALABAMA CITY, Birmingham Section

BRAKEMAN, Roy E. ('11), Engr., Charge Design, Gulf States Steel Co., Alabama City; *for mail,* 629 Turrentine Ave., Gadsden.

ANNISTON, Birmingham Section

CARRINGTON, Frank G. ('28), 1030 Christine Ave.

AUBURN, Birmingham Section

DIXON, Solon (J'27), Prof. M. E., Ala. Poly. Inst.; *for mail,* Box 2221.
HIXON, Chas. R. ('21), Asst. Dean, Prof. M. E., Ala. Poly. Inst.
WILMORE, John J. ('93), Dean Engrg., Ala. Poly. Inst.

BIRMINGHAM, Birmingham Section

BARR, Clarence D. ('15; '35), V. P., Am. Cast Iron Pipe Co., P. O. Box 2603.
BARRY, Jas. M. ('23), V. P., Charge Opera., Ala. Power Co.
BENTLEY, Geo. L. (A'21), Sales Engr., Ingersoll-Rand Co., 1700—3rd Ave., S.
BLAIR, Abbott H. ('27), Contracting & Engrg., 838 Martin Bldg.
BROTZMAN, Irvin C. ('28; '35), Supt., Lone Star Cement Corp., 1812 Comer Bldg.
BUELL, J. E. (J'33), Jr. Engr., Stockham Pipe Fittings Co., 4000 N. 10th Ave.; *for mail,* 2108 S. 11th Ave.
CAINE, Wm. P. ('99; '04; '18), 2215 Ave. H, Ensley Sta.
CARPENTER, Thos. J. ('19; '22; '35), Asst. Supt., Thomas Wks., Republic Steel Corp.
CLEM, W. Martin (J'34), Duke Bros. Furniture Co., 1816—3rd Ave.; *for mail,* Apt. 7, 3428—8th Ave., S.
COLE, Harry (J'27), Asst. Gen. Foreman, Tenn. Coal, Iron & R. R. Co., Birmingham; *for mail,* Route 1, Box 561, Bessemer.
CORK, Linn C. (J'34), Draftsman, Stockham Pipe Fittings Co., 4000—10th Ave., N.; *for mail,* 1515 N. 15th Court.
COTLIN, J. W. ('32; '35), 1119 N. 25th St.
DANIEL, Kenneth Rule (J'36), M. E., Am. Cast Iron Pipe Co.
DAVIS, Chas. Baker ('15), C. B. Davis Engrg. Co., 1000—43rd St., S.
DEARING, E. Richard ('24; '35), Designer, Tubize Chatillon Corp., Rome, Ga.; *for mail,* 631—9th Court, S., Birmingham, Ala.
DUGGER, Neal (A'18), Ch. Scale Inspr., Tenn. Coal, Iron & R. R. Co., P. O. Box 100, Ensley.
ESHELMAN, Jos. W. (A'26), Pres., Treas., Eshelman & Potter, 1116 Martin Bldg.
FRANCIS, T. M. ('25), Cons. Engr., 334 Brown-Marx Bldg.
FREEMAN, Henry Livingston ('17), Field Office Engr., Indus. Water Supply Comm., 501 Martin Bldg.; *for mail,* 2132—15th Ave., S.
GALLOWAY, Wm. S. (J'31), Lub. Engr., Sales Dept., Gulf Refining Co., New Orleans, La.; *for mail,* P. O. Box 737, Birmingham, Ala.
GETZEN, John E. ('25; '28; '35), Ch. Engr., Stockham Pipe Fittings Co.; *for mail,* 401 Yorkshire Dr.
GILFILLAN, John M. ('23), Owner, John M. Gilfillan & Associates, 416-17 Lyric Bldg.
GRACEY, Matthew, Jr. (J'36), Continental Gin Co.
GREAGAN, John J. ('17; '21), Dist. Mgr., Allis-Chalmers Mfg. Co., 815-16 Webb Crawford Bldg.
GULDBERG, Dan H. ('21; '35), M. E., Design & Constr., Am. Cast Iron Pipe Co.; *for mail,* 2321 Larch Ave.
HAMILTON, Wm. B. ('12), Prod. & Sales Engr., Hardie-Tynes Mfg. Co.; *for mail,* 1412 S. 17th Ave.
HAWN, R. J. ('13), V. P., Charge Opera., Monsanto Chem. Co., Anniston; *for mail,* 75 Mountain Brook Pkwy., Birmingham.
HEGENBARTH, Francis ('23), Sales Engr., Goslin-Birmingham Mfg. Co., Box 631.
INGALLS, R. I., Jr. (J'30), Jr. Engr., Birmingham Tank Co.
JACKSON, C. P., Jr. (J'34), 1027 S. 28th St.
JONES, Russell Eugene ('28), Ch. Engr., Birmingham Tank Co., 720—4th Ave., S.; *for mail,* 1136—10th Pl., S.
KENT, Herbert S. ('15; '18; '21), Sales Rep., Hays Corp. & Carrick Engrg. Co., Michigan City, Ind.; *for mail,* Homewood Sta., Birmingham, Ala.
MARSHALL, Emerson S. (J'36), 2619 Bush Blvd.
MERKEL, Arthur W. ('21), V. P., Charge Prod., Continental Gin Co., 4600—4th Ave., S.
MIDDLEMISS, G. H. ('18; '35), Mgr., Prod. & Trans., Commonwealth & So. Corp. of N. Y., 600 N. 18th St.
MOORE, Jas. W. ('17; '22), Mgr. Research & Engrg. Sales, Am. Cast Iron Pipe Co.
MOORE, W. D. ('21), Pres., Am. Cast Iron Pipe Co., P. O. Box 2603.
MOORE, W. Joe (J'33), Am. Cast Iron Pipe Co.; *for mail,* 207 Mecca Ave., Homewood Sta.
MOUAT, Harry G. ('23; '35), So. Mgr., Whiting Corp., 830 Martin Bldg.
MOXLEY, S. D. ('24; '26; '30), Ch. Engr., Am. Cast Iron Pipe Co.
O'NEIL, Robt. Dravo ('27; '36), Engr., Charge Branch Sales Office, Am. Meter Co., 447 Martin Bldg.
